CrossRef Publisher Linking Network

Amy E. Brand

CrossRef, Lynnfield, Massachusetts, U.S.A.

Abstract

CrossRef, the cross-publisher linking network and platform for other collaborative technologies and its services will be outlined in this entry. The impact it has had to date on various segments of the information industry and how it has progressed from a small DOI Registration Agency to a robust platform for publisher collaboration with tens of millions DOIs deposited in its system. CrossRef developments and new services will also be discussed, as will placing CrossRef as part of a larger trend in resource discovery toward virtual integration of distributed resources.

INTRODUCTION

This entry provides an overview of CrossRef, a cross-publisher linking network and platform for other collaborative technologies. It discusses CrossRef's mission and history, as well as how the system works, and the impact it has had to date on various segments of the information industry. A final section looks at recent CrossRef developments. The entry concludes by situating CrossRef as part of a larger trend in resource discovery toward virtual integration of distributed resources.

CROSSREF'S MISSION

CrossRef is a nonprofit membership association, founded and directed by publishers. Its mission is to enable easy identification and use of trustworthy electronic content by promoting the cooperative development and application of a sustainable infrastructure for online content. CrossRef operates a cross-publisher citation linking system, and is an official Digital Object Identifier (DOI) registration agency, appointed by the International DOI Foundation (or IDF).^[1] A look at the history of CrossRef helps explain these core functions of the organization.

CROSSREF'S HISTORY

CrossRef was incorporated in January of 2000 as a cooperative venture among 12 of the world's leading scholarly publishers, both commercial and not-for-profit, with a mandate to provide cross-publisher reference linking throughout the online journal literature. The founding members were Academic Press, the American Association for the Advancement of Science (publisher of *Science*), the American Institute of Physics, the Association for Computing Machinery, Blackwell Science, Elsevier

Science, the Institute of Electrical and Electronics Engineers, Kluwer Academic Publishers, Nature Publishing Group, Oxford University Press, Springer-Verlag, and John Wiley & Sons. Start-up funds for CrossRef were provided as loans from eight of the original publishers, all of which were paid off in full in 2007.

When the CrossRef service went live in June of 2000, it supported reference links in roughly 1100 journals from a member base of 33 publishers, using a beta system called the "DOI-X prototype."^[2] CrossRef became an official DOI registration agency in September 2000 and was the first such agency, authorized by the IDF to allocate DOI prefixes and register DOIs. To date, CrossRef is the most robust implementation of the DOI model.

Although CrossRef got underway with a specific focus on linking electronic journal articles in the scientific, technical, and medical (STM) arena, it has since branched out to cover DOI-based linking of all authoritative scholarly and professional literature online, regardless of genre or discipline, with a broader mission of improving resource discovery through collective initiatives.

The Importance of Cross-Publisher Linking

Among the visitors to the Frankfurt Book Fair in October of 1999 who witnessed a demonstration of the DOI-X project were several representatives from STM publishing. Recognizing that a DOI-based lookup system for citations could enable a cross-publisher article-level linking system for serials, they took the unprecedented step of joining together in an independent association.

Linking at the article-level benefits both scholars and publishers. References are how authors make explicit the links between their work and previously published scholarship. Making a citation immediately actionable, so that it links to the cited document in a matter of a click or two, is a powerful enhancement to efficiency and functionality in online research, but not if it is bounded by digital

collections defined by publisher. From the researcher perspective, neither the publisher's identity, nor even that of the journal in many instances, is considered a significant identifying feature of the published work, as opposed to who wrote it and when.

Hence, automated linking is mainly useful from a research perspective if it works across publications, across publishers, and is truly comprehensive. The usefulness of the system is directly proportional to the robustness of its coverage, and CrossRef paves the way for a truly robust, comprehensive network of connected publications.

Citation linking of this kind also offers advantages to serials publishers, because it drives readers to their publications and their Web sites. By allowing readers to connect to their content from outside resources and locations, they not only serve their subscribed user-base better, but at the same time they create opportunities for article- or chapter-based sales, whether through document delivery services, hosting intermediaries, or their own pay-per-view mechanisms.

CROSSREF TODAY

Let us look at how far the CrossRef initiative has progressed. As of October 2008, the network includes 619 publishers, 21,212 journals, and over 33 million DOIs, including 3 million DOIs for non-journal content such as books and conference proceedings, at varying levels of granularity. The CrossRef system is adding about 14,000 new DOIs every day. Many of these DOIs point to backfile, historical content, as publishers digitize archival material; roughly 400,000 CrossRef DOIs point to seventeenth, eighteenth, and nineteenth century publications. Another source for the steep growth is the addition of new content types. Publishers who have been registering journal content for some time now register DOIs for other resources, and new members who may not publish journals at all are joining to register books, proceedings, datasets, dissertations, grey literature, standards, and other scholarly materials.

The state of the CrossRef endeavor can also be measured by its impact on the research experience. Researchers are currently using the system at a rate of about 19 million DOI clicks per month. Roughly 5 million DOIs per month are retrieved from the system, which gives some indication of the number of DOI-based links being created. In addition to the 619 publishers who participate as members, there are roughly 3500 other participating organizations, including libraries, database publishers, full-text aggregators, software vendors, and journal hosting/linking platforms. These "affiliates" access the CrossRef database of DOIs and metadata on a regular basis to facilitate linking through their own products.

THE DOI^[3]

The DOI syntax is a National Information Standard Organization (NISO) standard.^[4] A DOI is an alphanumeric name for a digital content entity, such as a book, journal article, chapter, image, etc. The DOI is paired with the object's electronic address, or URL, in a central directory that can be readily updated, and is published in place of the URL to prevent links from breaking, while allowing the content to move as needed. The CrossRef system makes updating the URL in the central DOI directory very easy. Since CrossRef publishers have been updating their records reliably so far, reports of nonworking DOIs are rare, even with millions of DOIs being resolved each month.

Let us take a closer look at a DOI, in Fig. 1. The DOI is made up of two components, a prefix and a suffix, separated by a forward slash. The prefix is assigned to the content owner by a DOI registration agency like CrossRef. All DOI prefixes begin with "10" (to distinguish the DOI from other implementations of the Handle System®),^[5] followed by a four-digit string. The prefix in this example is "10.1006." The suffix has a very flexible syntax and is composed by the publisher according to their internal content management needs, with the main restriction being that the suffix must be unique within a prefix.

Once a DOI is assigned to a digital entity, it continues to identify that entity regardless of ownership. While publishers assign DOIs using their own prefix(es), control of individual DOIs can be readily transferred. For example, if ownership of a journal passes from Publisher X to Publisher Y, control over the DOIs for articles in that journal will be given to Publisher Y, who can then update the metadata and URLs for those DOIs. Publisher X will continue to assign DOIs using their existing prefix. Therefore, the prefix of a DOI does not reliably identify the publisher. At the same time, because the DOI never changes in these cases, it means that all the links to that content that have already been published still function. Hence, one key insight of the DOI system is persistence; the other is "actionability." Like the URL itself, one click on a properly implemented DOI gets the user to the location of the content they want.

The DOI remains unique and persistent throughout changes in ownership and location of the content, but it need not be transparently meaningful or descriptive. Rather, descriptive information belongs in the metadata

Fig. 1 Sample DOI, illustrating prefix and suffix.

associated with each DOI when it is registered in the CrossRef system. Actionable, persistent identifiers like the DOI add value to publications because they enable new functionality and work reliably in the Web environment. The identifier strings themselves can be opaque if they are associated with descriptive metadata in the registration process, and, in any event, mainly being interpreted and processed by computers. At the same time, registering an identifier along with descriptive metadata lays the groundwork for constructing other automated services around the content being identified.

HOW CROSSREF WORKS

Publishers use automated (i.e., batch) processes to deposit metadata records into the CrossRef metadata database (MDDb). Each deposited record must include minimal bibliographic information, a DOI, and a current URL. The descriptive metadata includes journal title, ISSN, first author, year, volume, issue, and page number. Depositing metadata with CrossRef involves creating an XML file formatted according to a schema. A sample CrossRef metadata record with both journal-level and article-level metadata and identifiers is shown in Fig. 2.

When publishers deposit records, they automatically enable others to link to their content, because other publishers, librarians, and intermediaries can then retrieve from CrossRef the DOIs that link to that content. After a metadata record is deposited, CrossRef registers each DOI-URL pair in the central DOI directory, an implementation of the Handle System. Thus, when a user clicks on the DOI, it is resolved through the Handle System and not the CrossRef system.

In a separate process, the publisher submits the citations contained in each registered work as queries to the MDDb in order to retrieve any matching DOIs. This way, the publisher can, as part of its electronic production process, add outbound hyperlinks to any of an article's citations that point to entities already registered in the CrossRef system. CrossRef can also accept DOIs as input and return metadata as output. Fig. 3 provides an overview of the workflow for reference linking.

Non-XML interfaces for depositing and querying are now also available. A manual Web deposit form allows publishers to type in requested metadata on a record-by-record basis, and a simple text query form allows publishers and other users to cut and paste groups of references in order to retrieve matching DOIs. These services have helped make the CrossRef system readily accessible

Fig. 3 Workflow for reference linking.

to smaller content providers, including those with limited resources and technical expertise.

When metadata and DOIs are deposited with CrossRef, publishers must have active response pages in place so that they can accept incoming links. As soon as a given deposit goes through, other users of the system will be able to retrieve the DOI in question and create links using that DOI. A minimal response page consists of a full bibliographic citation and some mechanism via which the user can gain access to the

full text. Access to proprietary content is controlled by the publisher; most publishers take users to an abstract page and permit authenticated users to go directly to the full text. If the full text is available at no charge, all users can view it immediately. Many publishers also present unauthenticated users with pay-per-view options.

Fig. 4 shows a user clicking on a CrossRef DOI in Journal 1 and connecting to a response page at the Web site of Journal 2.

Fig. 4 DOI resolution from the end-user perspective.

In sum, CrossRef provides a database of DOIs and metadata that supports DOI lookup. If you know the DOI for a piece of content, that is all you need to know in order to locate it persistently, not unlike a homing device. If a publisher changes the location of the content, it need only update the URL in one place.

CROSSREF'S IMPACT

Let us look now to how CrossRef impacts the various communities in the information arena.

Impact on Publishers

The current system of Internet addressing made widespread linking possible several years ago. Yet cross-publisher linking remained a largely onerous and error-prone endeavor for scholarly publishers until CrossRef was formed. Before CrossRef, in order to link with one another, publishers had to enter into numerous bilateral agreements and stay on top of several publisher-specific, algorithmic linking schemes. Any change in the online location of a piece of linked content meant that previously published links to that content became obsolete.

With CrossRef, publishers have both a technology and a business infrastructure for persistent linking. On the business side, the publisher (or other interested party) signs one agreement with CrossRef and gains the right to link to all other participating publishers. With 619 dues-paying members, nearly 200,000 bilateral agreements ($1/2N(N - 1)$) would have otherwise been needed to enable the same network of connections. Hence, a linking network on this scale could never have arisen without an organizational infrastructure like CrossRef. Publishers also benefit from being part of a collaborative platform for ongoing development of shared technologies, while maintaining control over their own business practices and how their content is accessed.

On the technology side, CrossRef addresses the error-proneness of links by use of the DOI, as described above. CrossRef is the only DOI registration agency with a DOI lookup and retrieval service. For a publisher with content registered in the CrossRef database, this means that over 3500 participating organizations—other publishers, A&I databases, aggregators, and libraries—will be able to link automatically to their response pages. For electronic books such as reference works, CrossRef facilitates internal linking of components and references, as well as providing durable hyperlinks from citations to any other participating publishers' material. Assigning DOIs to book chapters gives publishers a head start in repurposing content for course-packs, for derivative works requiring a subset or reordering of the original components, and for e-commerce at the chapter level.

Impact on Libraries

With CrossRef functioning as intended, DOIs are now widely distributed by publishers as a standard part of bibliographic metadata. Libraries and their patrons regularly encounter DOIs in the primary and secondary publications that they access. DOIs are good for libraries in the same way that they are good for the research process. Namely, they make linking reliable at any level of granularity possible. In the same way that links drive readers to publisher content, libraries may also see increased usage of acquired electronic resources as an additional benefit.

Most researchers access content through the institutions with which they are affiliated. For the user working in an institutional context, it is not always appropriate to be directed to publisher's online version of a research article. For instance, the institution may not subscribe directly to the e-journal but may still be able to offer the user access to the desired article through an aggregated database or through print holdings. In addition, the library may wish to provide a range of navigational options beyond what is available at the publisher's Web site.

The OpenURL is a mechanism for transporting metadata and identifiers describing a publication, for the purpose of context-sensitive linking. The OpenURL standard has been NISO accredited (ANSI/NISO Z39.88) since 2004.^[6] A "link resolver" is a system for linking within an institutional context that can interpret incoming OpenURLs, take the local holdings and access privileges of that institution into account, and display links to appropriate resources. A link resolver allows the library to provide a range of library-configured links and services, including links to the full text, a local catalog to check print holdings, document delivery or ILL services, databases, search engines, etc.

The DOI and the OpenURL work together in several ways. First, the DOI directory itself, where link resolution occurs in the CrossRef platform, is OpenURL-enabled. This means that it can recognize a user with access to a local resolver. When such a user clicks on a DOI, the CrossRef system redirects that DOI back to the user's local resolver, and it allows the DOI to be used as a key to pull metadata out of the CrossRef database, metadata that is needed to create the OpenURL targeting the local resolver. As a result, the institutional user clicking on a DOI is directed to appropriate resources.

By using the CrossRef DOI system to identify their content, publishers in effect make their products OpenURL aware. Since DOIs facilitate linking and data management processes for publishers, many publishers are beginning to require that the DOI be used as the primary linking mechanism to full text. Link resolvers can use the CrossRef system to retrieve the DOI, if the DOI is not already available from the source (i.e., citing) document.

As we have seen, static URLs are not a persistent linking mechanism. If a URL is published as a link and the content it points to is moved, then that link will no longer

function. DOIs address this problem. An OpenURL link that contains a DOI is similarly persistent. OpenURLs without DOIs can function persistently only if the relevant metadata is updated within the institution's link resolver. This process is greatly streamlined via access to the CrossRef system, because CrossRef provides a single source for linking reliably to a multitude of publishers without the need to track varied metadata-based linking schemes. In short, link resolvers benefit from using the DOI when linking to publisher-designated resources is appropriate, and as a way to obtain needed metadata.

Impact on Intermediaries

CrossRef encourages its publisher members to distribute DOIs as part of the standard bibliographic metadata that they provide to database publishers, aggregators, vendors, and other intermediaries. These intermediaries can also come directly to CrossRef for a way to identify, acquire, and capture DOIs for records that do not currently contain DOIs as provided directly by the primary publisher.

Like primary publishers, intermediaries join CrossRef to create links to all CrossRef member publishers without signing bilateral linking agreements or having to track publishers' individual linking schemes. They can then also offer their customers links to the full-text content of some primary publishers who do not authorize any other type of linking relationship. In addition to the efficiencies of centralized linking agreements and the enhanced utility of indexes that link reliably to full-text resources, some intermediaries offer CrossRef implementation as part of their journal hosting services, and others integrate their own software into the CrossRef system.

Impact on Researchers

Clearly, researchers want the content that they read online to be linked. It is much more efficient to navigate a body of research at the citation level. When the researcher takes on the author role, linking can be viewed as a way of garnering additional exposure. Including outbound hyperlinks adds valuable functionality to online publications, and inbound linking increases readership and citations. Although the CrossRef linking infrastructure has not been actively promoted to the end user, researchers are increasingly aware of DOIs, and CrossRef now offers several free points of access for researchers to retrieve DOIs. Many scholars and scientists now add DOI links to their own authored works, whether journal articles or newer communication formats such as blogs.

BEYOND CITATION LINKING

The CrossRef network is currently expanding not only in terms of content coverage—to different genres and levels

of granularity—but also in terms of functionality. Some of the latest key developments are described here.

Cited-by Linking formerly Forward Linking is a way of tracking citations to a given publication as they occur. In addition to using CrossRef to create outbound links from their references, CrossRef member publishers can now retrieve “cited-by” links—links to other articles that cite their content. An optional tool is offered to CrossRef members, enabling them to display “cited-by” links in the primary content that they publish. This is a natural extension of the CrossRef linking network, and helps provide a better online reading environment for researchers and scholars. As part of the same functionality, CrossRef also offers a “match-alert” feature that saves users from having to query CrossRef repeatedly to find DOIs for citations that do not initially return a match. If the publisher chooses to enable this, then the system automatically sends an e-mail containing the matched results when the relevant content is registered in CrossRef.

CrossCheck powered by iThenticate^[7] is a new initiative from CrossRef to help the scholarly publishers verify the originality of submitted manuscripts. The need of a plagiarism tool was identified as a top priority by CrossRef members in 2006 and as a result CrossRef researched the best plagiarism tools on the market to provide a solution for the CrossRef members. CrossCheck is really two products, a database of scholarly publications and a Web-based tool to check an authored work against that database. The Web-based tool can be used in the editorial process to identify matching text but it cannot, on its own, identify plagiarism. A human has to look at the matching text and use their best judgment to identify if plagiarism has occurred or not.

CrossRef Metadata Services formerly CrossRef Web Services is an optional service for publishers who would like CrossRef to disseminate metadata on their behalf. This can be useful to streamline the Web crawling carried out by search engines and others, in order to optimize the functionality of their indexes. It consists of a suite of tools to enable authorized partners to collect metadata from multiple publishers, using a variety of metadata gathering implementations such as Open Archives Initiative Protocol for Metadata Harvesting (OAI-PMH). Standard terms of use are provided for search engines, libraries, and other partners to use the metadata available from CrossRef Metadata Services.

CONCLUSION

CrossRef is about reducing friction in the means of discovering and accessing scholarly content online. Perhaps the key insight of the CrossRef initiative is that it allows publishers to create collectively the experience of integrated electronic resources for the scholarly community,

without in fact requiring aggregation of anything but the most minimal metadata.

CrossRef is representative of a trend toward “distributed integration”^[8] of information resources that will continue to progress as publishers take advantage of yet other ways, such as the Open Archives Initiative,^[9] to expose metadata about their information products on the Web for harvesting, search, and e-commerce applications. From the end-user perspective, the outcome is a more highly integrated body of research literature, even if such integration is merely virtual. As the automated tools for exposing and harvesting metadata, classifying content, and performing intelligent search continue to be refined/improved, this trend will no doubt advance.

Interlinking of resources across publisher platforms, as in CrossRef, is a prime example of distributed integration in electronic publishing. Both content providers and content consumers benefit from initiatives that use metadata and identifier registration to enable virtual integration of scholarly literature online.

Cultural Memory

Robert DeHart

Department of History, Middle Tennessee State University, Murfreesboro, Tennessee, U.S.A.

Abstract

Cultural memory is a term used to describe interpretations of the past created by a group to address contemporary concerns. Cultural memory is transmitted to other individuals in forms such as commemorations, rituals, monuments, oral traditions, museum exhibits, books, and films. Groups or nations create and transmit cultural memory primarily to promote unity, identity, or some other political or cultural ideal. The term traces its origins to anthropology, but sociologists developed its theoretical framework. Since the 1980s, a number of academic disciplines have embraced cultural memory studies as a valuable tool of inquiry. Although it is a popular field of research, critics contend that a number of methodological issues need to be resolved. The term has entered the popular lexicon to describe how the works of a contemporary generation utilizes the traditions of a previous generation.

INTRODUCTION

Cultural memory is a term used to describe interpretations of the past shared by a group of individuals. The need to address contemporary concerns, such as preserving group identity or sustaining support for a political ideal, influences the creation and content of cultural memory. Thus cultural memory represents a reconstructed past that serves the present needs of a group. Individuals that construct, support, or preserve cultural memory usually share nationality, religion, ethnicity, politics, or some other cultural identifier, and many times these individuals did not live through the event being remembered. A group's cultural memory is reinforced and transmitted to other individuals in forms such as commemorations, rituals, monuments, oral traditions, museum exhibits, books, and films.

Scholars in fields as diverse as history, religious studies, literature, folklore, art, anthropology, sociology, and mass communications have devoted considerable research and texts to the significance of cultural memory to their respective fields. The term cultural memory has also entered the popular lexicon. It is sometimes used to describe how activities such as cooking, composing popular music, and graffiti reflect aspects of a culture's past traditions.

HISTORICAL CONTEXT AND TERMINOLOGY

Although the term "cultural memory" was not coined until the 1980s, its theoretical framework came to light during the upheaval that occurred in the humanities following the devastation caused by World War I. In an attempt to understand the ethnic, social, and political dynamics that led to the conflict, scholars sought new methods for

analyzing the inner ethnic relationships and international relations of nations. From this scholarship emerged new ideas about memory distinct from its Freudian conception as created and existing purely in the minds of individuals. The scholar most frequently cited as forming these ideas into a usable theory is French sociologist Maurice Halbwachs (1877–1945). His book *Les cadres sociaux de la memoire* (The Social Frameworks of Memory), published in 1925, theorized that individuals reconstruct memories of the past only within a social context. Through day-to-day communication individuals possessing shared concerns for the present form memories of the past "collectively" that supports the needs of the group. He labeled this type of memory "collective memory." To support his theory, he demonstrated how different classes of French society (working, old wealth, new wealth, etc.) collectively possessed contrasting interpretations of French history.^[1,2]

Halbwachs' ideas influenced scholars in the ensuing decades, but none had quite the impact on the development of cultural memory theory as French historian Pierre Nora. His *Lieux de Memoire* series (Realms of Memory), first volume published in 1984, solicited essays from a number of French historians that identified and examined historic and cultural sites that represented collective memories. For example, contributor Edouard Pommier demonstrated how during the late 1600s King Louis XIV employed decorative arts in the Palace of Versailles to link his reign with heroic legends of antiquity. In the process, the King hoped to fuse French history with myth to create an idealized vision of the French past that would support his administration.^[3] This essay and others in the volumes for the first time placed collective memory into a broad historical context, thus establishing it as a characteristic of modernity (the era beginning in Western Europe in the 1600s that embraced science and reason as the tools to

propel civilization toward an ever-evolving state of progress). Nora contended that modernity and its emphasis on nation-building and industrialization had created a divide between peoples' personal experiences and their relationships to the past, especially when it came to identifying with a national or cultural ideal. Thus, a need arose for producing "external sites of memory" such as monuments and museums to preserve links between individuals and tradition. According to Nora, this "memory crisis" was further exasperated in the twentieth century with the ascendancy of popular culture and emergence of postmodernity (generally referring to the era following World War II; proponents of the term rejected the notion that civilization was in a state of continuous progress). Popular culture, such as television shows, popular music, and films, increasingly defined the shared traditions of groups, thus creating an even greater need to locate ways to preserve national and cultural traditions.^[1] Nora's work had enormous influence on the potential applications of collective memory theory, leading a new generation of scholars into the field of cultural memory studies the following decade.

However, the term "collective memory" did not sit well in all disciplines. While sociologists naturally gravitated to the term in their work, scholars in other disciplines, especially historians, developed alternative terminology that better reflected their methodological framework. They employed terms like public memory, social memory, popular memory, heritage phenomenon, patriotic culture, cultural amnesia, and myth to describe what are at their core Halbwachs' original conception of collective memory. This different vocabulary had more to do with the type of research being conducted and enhancements of definition rather than a major break with the sociological foundation of collective memory.

Perhaps the most widely used memory term in academia and popular culture is "cultural memory." A frequently cited definition of the term emerged from the field of anthropology by German Egyptologists Jan and Aleida Assmann. In Jan Assmann's book *Kultur und Gedächtnis* (Culture and Memory), published in 1988, he expanded on Halbwachs' work by locating two primary modes of collective memory. Assmann defined "communicative memory" as the day-to-day communication of individuals that expresses shared viewpoints about the past. This memory has no fixed place in time and thus lasts only a few generations. "Cultural memory" is when these "communicative memories" are turned into "objectified culture," such as monuments, texts, and museums. Only then do the memories become fixed in time, become distanced from everyday communication, and achieve power.^[4] To illustrate the differences between these two types of memory, imagine an American family who shares and discusses its memories of President Franklin Roosevelt's New Deal programs of the 1930s. Aspects of these memories may shift over time as some details gain or fade in importance

and the generation who lived through the era dies off. At this point, these memories would be defined as communicative. But if the family creates a text or commemoration that reconstructs its memories of the New Deal, and if this text or commemoration becomes accessible to the public, it becomes a cultural memory that can be shared with other Americans.

CHARACTERISTICS OF CULTURAL MEMORY

Defining the Group

An interesting aspect of cultural memory is that there is no formula for determining the makeup of a group who shares or creates a cultural memory. This is not to say that cultural memories do not frequently form along cultural indicators such as ethnicity and class. But it would be an oversimplification to point to this as one of its defining characteristics. Cultural memories can exist and be produced in units as small as ethnic minorities, created by the bureaucracy of a nation, or shared across lines of class and nationality. In fact, in the late 1990s the Getty Institute initiated a "Global Cultural Memory" project to "create a collective archive of digital information (text, images, and, in future, sound and video) that documents both everyday and singular events, lifestyles, and achievements that have influenced the most recent 50 years of cultural memory."^[5] It is hard to imagine an application of cultural memory that could have a farther reach.

Age is one important indicator for understanding why one group may find an aspect of the past important for commemoration while another group may choose a different past. Psychologists Schuman, Rieger, and Scott conducted studies in 1989 and 1992 that sampled 1410 Americans over 18 years old. Participants were asked to name past public events that they deemed as important to their lives. The study found that events that occurred when participants were in their late teens or early twenties appeared to receive the largest positive response. Thus, for an event like the assassination of President John F. Kennedy, people who were in their twenties when the event occurred found it to be more significant to their lives than people who were in their fifties (Fig. 1). This suggested that people of the most affected generation would likely support commemorations, museums, movies, etc. that showcase the event more than earlier or later generations. The study is also significant for the number of people who recalled significant events that occurred well before they were born. In the case of the Depression of the 1930s, 10% of participants deemed the event as important to their lives even though they were not born until 29 years after the event occurred (Fig. 2). For these respondents, such is the strength of the cultural memory of the Depression that had been transmitted to them by family, texts, the media, and other sources.

Fig. 1 John F. Kennedy's death.

Source: From Schuman and Rieger, C.^[21]

Considering that many cultural memories form out of a need to establish group identity and unity, ethnicity is an important indicator. A study by Roy Rozenzweig and David Thelen, published in 1998, revealed how black and white Americans possessed very different views of U.S. history. When asked to list past events that had been important to their lives, a majority of black participants listed the Civil Rights Movement first and slavery as second. In contrast, white participants listed World War II first and the Vietnam War second (Table 1). This survey helped explain why the cultural memory of nations is so often contested. Various interest groups possess strong opinions as to what aspects of a nation's past are worth commemorating. When the preservation of that past is in jeopardy or not supported by the nation's leaders or other groups, conflict almost certainly ensues.

While interest groups form their own cultural memories of the past, nations often use cultural memory to promote particular policies. The majority of scholarly texts that focus on this aspect of cultural memory deal with contemporary issues, but scholars have been successful in demonstrating that manipulations of cultural memory by nations existed already in antiquity. Jan Assmann argued that the leaders of the ancient Egyptian Middle Kingdom (2040–1650 B.C.E.) used cultural memories of the leaders of the preceding First Intermediate Period (2150–2040 B.C.E.) to help establish their authority over

Fig. 2 The depression.

the Egyptian people. The First Intermediate Period was a time of extreme chaos and uncertainty in Egypt. With its enemies defeated by the time of the Middle Kingdom, the new rulers needed to preserve the memories of the earlier period to demonstrate that “only the [current] pharaoh could restore order and balance in a world out of joint and threatening to fly apart.”^[6] Assmann used surviving texts from the Middle Kingdom that evoked these disturbing memories to support his theory that cultural memory is not unique to modernity.

To cite a contemporary example, American historian John Bodnar employed the rubric of public memory to examine how the battles surrounding the monuments and museums commemorating the social and political upheaval of Vietnam War/Civil Rights era America paralleled the turmoil of the 1960s itself. He viewed public memory as an “intersection of official and vernacular cultural expressions.” Official culture represented the goals and beliefs of national leaders seeking unity, while vernacular culture represented the localized beliefs of various specialized interests.^[7] Together they competed to form a public memory of the past that could be widely accepted yet serve the interests of each group. The tendency of a nation to manipulate the past as propaganda to support its agenda and the efforts of minority groups to contest this reconstruction of the past by asserting its positions is a recurring theme in the literature produced by historians exploring cultural memory.

Impressively, some cultural memories have the ability to reach across generational and ethnic lines with little contestation within a nation. A good example is the American cultural memory of the Holocaust. Although a minority of Americans was personally affected by the atrocities against Jews carried out in Adolf Hitler's Germany during the 1930s and 1940s, America possesses a number of museums devoted to the genocide, and dramatic portrayals in film and television have persisted in popularity. As historians Peter Novick and Michael Morgan have observed, the rise of a Holocaust consciousness in Jewish Americans, which occurred decades after the event actually happened, stemmed from a need to provide unity in the Jewish American community in light of declining religiosity and increasing assimilation. The Holocaust also provided

Jewish Americans a link with Israel. But in America, the story of the Holocaust was created somewhat uniquely from stories generated in Israel. American museums embraced a “universalist definition” of the Holocaust that linked Jewish victims with those of other ethnicities and nationalities killed by German sponsored pogroms during World War II. Some even went as far to link the genocide with other atrocities such as the “killing fields” of Cambodia during the 1970s or the slaughter of Armenians by Turkish soldiers during World War I, thereby removing anti-Semitism from its central place in the narrative (a fact that incensed many Jewish scholars). Scholars opine that America embraced this definition because it would better resonate with the nation’s diverse population, address the societal need for tolerance, and perhaps even deflect attention from America’s own history of racism.^[8,9] The embedment of the Holocaust into the American consciousness has been very successful. Regardless of class, ethnicity, or religion, many Americans possess a shared knowledge of the event through museums like the National Holocaust Museum and Museum of Tolerance, films such as *Schindler’s List*, and popular books like the *Diary of Anne Frank*.

Representations

As described above, representations of cultural memory may be found in museums, archives, monuments, commemorations, film, and books, and historians have made good use of this primary source material to explore how groups reconstruct the past. But representations of cultural memory can take many forms and many other disciplines have used cultural memory theory to good effect. Anthropologists found cultural memory theory to be an effective way to investigate non-Western cultures. Rejecting the use of nineteenth century colonial records to understand such cultures, anthropologists turned to observations of indigenous people “in the field” and recognized how cultural memory was deeply embedded in contemporary traditions. Utilizing this approach revealed that historical interpretations of the past existed in these cultures in a non-linear fashion, distinct from the linear properties of history in the West. For example, Levi-Strauss observed Australian aborigines performing historical or commemorative rites that recreated the sacred and beneficial atmosphere of mythical times to recall the traditions of their ancestors.^[10] Rather than a simple reenactment of the past, the aborigines viewed these rites as allowing the past and the present to coexist simultaneously. These rites, which can be interpreted as cultural memories, served to reinforce identity and support social needs.

In literary criticism, scholars have used cultural memory theory to locate meaning in fictional characters. A critique of Paule Marshall’s novel *Praisesong for the Widow* by Susan Rogers invokes cultural memory theory to analyze the book’s protagonist Avey Johnson. A woman of African

American and Caribbean heritage, Johnson becomes obsessed with reconnecting with her African ancestors’ history of bondage in the Americas. In her essay, Rogers explored how the author portrays Johnson’s body as “a site of cultural expression and memory.” Feeling detached from life and in denial of her heritage, Johnson struggles to find her true identity during an ocean cruise eventually rediscovering a sense of heritage in one of the oldest forms of cultural memory—the dance.^[11]

Art historians have long recognized that artworks transmit the culture of the past to contemporary societies. Before Halbwachs developed his theory of collective memory, German art historian Aby Warburg (1866–1929) used anthropological methods to deconstruct art works and reveal connections between an artist’s work and its social and historical contexts. Unlike many of his contemporaries, he rejected the analysis of art based purely on aesthetic principles. But he also warned against expecting too many insights into the artist’s world by just looking at his or her artwork. For Warburg, all culture transmitted through art was mediated in some respect and “artistic style is a most treacherous key for ascertaining political and social developments.”^[12]

The interdisciplinary fields of American Studies and Cultural Studies have embraced cultural memory theory as a method of investigation. Popular culture provides much of the source material for these fields to explore the lives of ordinary citizens. Hip Hop music, Tom Cruise movies, graffiti at the Beatles’ Abbey Road recording studio, and the *X-Files* science fiction TV show have all been used as source material for uncovering cultural memories.

In journalism, cultural memory as a term is sometimes used in articles and reviews. A kind of jazz may invoke a cultural memory of the big band era of the 1930s. A particular dish may produce the cultural memory of an ethnic cooking tradition. Even commemorative journalism that reports on observations of historic events draws on cultural memory theory. The meaning of cultural memory as originally defined by Assmann has likely been misused by some in the media. Nonetheless it has found wide-spread acceptance as a descriptor of the ethereal mnemonic qualities of things that pass from generation to generation.

Social Relevance

As these examples illustrate, the need to address contemporary concerns influences the creation and transmission of cultural memory. Thus, scholarly investigation of cultural memory possesses significant implications for the present. According to one critique, it appeals to scholars because it “turns academics into concerned citizens who share the burdens of contemporary memory crises.”^[13] Or as historian John Gillis explained, it locates “usable pasts capable of serving the heterogeneity of new groups that

[have] become active on the national and international stage: racial and sexual minorities, women, youth, and dozens of new nations and ethnic groups aspiring to sovereign status.”^[14] Through an examination of how groups reconstruct the past, the core issues that divide and unite people can be revealed.

The preservation of the Lorraine Motel in Memphis, Tennessee, site of the 1968 assassination of Civil Rights leader Martin Luther King, Jr., shows how cultural memories expose divisions in society and influences the urban landscape. The assassination was so shameful to the city of Memphis that it took 20 years before major efforts went forward to turn the Lorraine into a museum. But even then, city residents possessed strong opinions about whether this cultural memory deserved recognition, and opinions were divided along mostly racial lines. Most blacks felt that a museum at the Lorraine would help heal societal wounds caused by the city’s history of racial discrimination and uplift the black community by recalling its role in the national Civil Rights movement. In contrast, most whites felt that the museum would only reignite the racial unrest of the 1960s. Some also felt that King’s legacy was not worth remembering because of his opposition to the Vietnam War and his stances on economic equality (seen by some as an obvious reference to Communism).^[15] In sharp contrast to the ease at which Holocaust museums found a foothold in America, Civil Rights museums have met resistance. The National Civil Rights Museum at the Lorraine eventually opened in the early 1990s and helped revitalize a section of downtown Memphis. An examination of the cultural memory conflict that occurred in the city during the museum’s development proved to be an effective way for understanding the city’s unresolved racial issues.

The social relevance of cultural memory is not a uniquely Western phenomenon. According to historian Gyanendra Pandey, beginning in the 1980s in India, a right-wing Hindu movement waged an effort to establish a national Hindu culture in the nation. Naturally, the movement focused on reconstructing history and memory to achieve its goals. The movement reclaimed national sites by tearing down historic mosques, built monuments to its leaders, and produced a widely distributed pamphlet that featured a “new” history of India that highlighted the heroic contributions of Hindus to the nation.^[16] In modern China, Ban Wang sees the occurrence of a “dialectic tension between memory and history” to form a contemporary national memory. On one hand, the traumatic memories of imperialism that were used to justify the creation of an authoritarian state in China are being subdued to accommodate the economic benefits of the nation’s movement into the global marketplace. But on the other, nostalgia combined with a critique of modernization attempts to hold enthusiasm for a Chinese global economy in check. Thus, according to Wang, history and cultural memory in China are in transition as current

discussions about the direction of the nation create a need to reform cultural memories of the past.^[17] Both of these examples underscore how present political or societal needs influence the reconstruction of the past in nations around the globe.

CRITICISMS OF CULTURAL MEMORY STUDIES

Since the 1980s, cultural memory studies have produced a flood of academic manuscripts and popular cultural references. However, a number of scholars have raised their voices to express concern about the inherent problems with drawing precise conclusions from cultural memory studies. One such concern is that too little attention is paid to how cultural or collective memory is different from individual memory and that scholars sometimes misapply psychoanalytical tools developed for understanding individual memory to the shared memories of groups. Terms familiar to discourse on individual memory such as “trauma” and “amnesia” are frequently used in conjunction with cultural memory theory, but questions persist if these same terms can be properly applied collectively rather than individually (p. 186).^[2] Take for example the memories created by natural disaster such as Hurricane Katrina, which hit the United States in 2005. An individual who lived through the event may experience mental trauma. This individual might repress memories or manipulate them to deal with the trauma. These memories may even change over time as the temporal distance increases from the event. At the same time, other population samples of the United States, who are concerned by the disaster’s implications for national image, may be said to have also experienced trauma from the event. But is the trauma experienced by the individual and the population sample the same? Can we accurately interpret the trauma experienced by the United States as a whole? To some scholars, cultural memory studies too frequently fail to make this distinction and treat the shared memories of groups the same as the memory of an individual. They believe that more work needs to be done on how collectives truly manage to remember and forget.

The lack of understanding of how groups receive and internalize specific representations of cultural memory is another major concern for critics of cultural memory theory. Cultural memories, as represented by monuments, museums, etc., tell us much about the people who created them, but little is known about how these memories move from monument to individuals and eventually groups. Individuals invariably bring their own interpretations of the past with them as they encounter a museum exhibit or historical film. The effect of this interplay on cultural memory is rarely addressed. Receivers of cultural memories do express opinions in newspaper editorials and other sources that provide access to the thoughts of these receptors, but even these sources are mediated by editors and do

not present an unmediated representation. Wulf Kansteiner suggests that one solution to this problem would be to look at why some memories never succeed in becoming a part of a public consciousness. An example he cites is the commemoration of America's involvement in the Korean War. "The Forgotten War," as it is sometimes called, finally received some attention during the 2000s with street names and memorials in cities across the nation paying respect to the soldiers who participated. But this was after memorials for veterans of the Vietnam War, which ended two decades after the conclusion of the Korean War, had already appeared. For Kansteiner, examining why some events fail to become part of cultural memory may be as illuminating as looking at the ones that succeed.^[2]

According to some critics, the similarities and distinctions between the reconstruction of the past that occurs during the formation and transmission of cultural memory and the scholarly process of producing historical texts and media needs to be explored further. Groups create cultural memory by manipulating viewpoints about the past to address contemporary concerns. The biases and current interests of historians naturally influence the subject matter and interpretation of historic persons and events found in their work. Indeed historiography is full of examples of multiple changing perspectives on historical events. This leads to the question as to what are the true distinctions between cultural memory and history. Is it simply the academic status of history that distinguishes it from the building of museums and monuments? Are not the public historians who build the collections in museums or develop historic sites deemed as professionals?^[1] The cultural memory versus history debate remains unresolved.

Some scholars have also noted how the majority of cultural memory studies focus on controversial historical events and contestation. Volumes have been produced on memory conflicts regarding the Holocaust, American Civil War, French Revolution, and post-World War II Germany. The more divisive a history, the more reconstruction of cultural memory appears to come into play. However, in cases where remembrance has provoked little controversy, memory studies are typically silent. The Lorraine Motel represents a site of contentious memory, thus its preservation has been analyzed. But most likely a nineteenth century Victorian house in Memphis preserved for its architectural beauty will receive little attention in regards to the cultural memory that it represents. Psychologist Barry Schwartz argued that cultural memory studies begin to ring hollow unless

...there is something to be mystified, some injustice or atrocity to be concealed. . . . In every culture and in every age we see exclusion and bias, but as the work of civil rights, multiculturalism, and inclusion continues, it becomes more difficult to squeeze out insights from [cultural memory] analysis.^[18]

According to Schwartz, cultural memory studies could conceivably reach a point where it runs out of source material for study.

CONCLUSION

Despite criticisms of cultural memory theory, the use of the term cultural memory in academia and popular culture shows no sign of abating. The term persists as a way to identify reconstructions of the past created by groups or nations. Cultural memory is transmitted to other individuals in forms such as commemorations, rituals, monuments, oral traditions, museum exhibits, books, and films. Thus these forms supply the primary source material for scholars to investigate the implications and significance of cultural memory creation and transmission. The term traces its origins to anthropology, but sociologists developed its theoretical framework. Since the 1980s, a number of diverse academic disciplines have embraced cultural memory studies as a valuable tool of inquiry.

There are three main characteristics of cultural memory. First, diverse groups create and share cultural memories. There is no formula for defining the size, age ranges, ethnicity, or nationality of groups that may create or possess a cultural memory. Cultural memories frequently form along such cultural indicators, but there are examples of cultural memories that transcend this pattern. Scholars have located examples of cultural memory creation in cultures across the globe in both antiquity and modern times.

Second, representations of cultural memory occur in many forms allowing many academic disciplines to apply cultural memory theory. Historians, in their work, emphasize cultural memories transmitted through commemorations, monuments, and museums. Cultural memory may also be located in forms such as religious practices, visual arts, literature, dance, and music. Although the term is used by the popular media in a slightly different context than it is in academia, it is sometimes used by journalists to describe how a generation utilizes the traditions of a previous generation.

Third, cultural memory is created to address contemporary concerns. Thus, cultural memory studies possess social relevance because it contributes to an interpretation of national culture and reveals the core issues that divide and unite contemporary populations. Cultural memory influences preservation initiatives that affect the built environment and underscores the challenges faced by nations as they strive for continuity during times of change. As a result, contestations between groups and nations over representations and manipulations of cultural memory are a core aspect of cultural memory literature.

Critics contend that a number of methodological issues need to be addressed before cultural memory theory can emerge as a reliable tool of inquiry. Scholars sometimes

misapply psychoanalytical tools developed for understanding individual memory to the collective memories of groups. How groups process and receive reconstructions of cultural memories has not been fully explored. Some scholars are troubled by the relationship between cultural memory studies and historical research. And, the study of cultural memory tends to focus primarily on contentious events.

The number of articles discussing cultural memory has declined since the 1990s. However, commemorations, monuments, and other interpretations of the terrorist attacks of September 11, 2001 will undoubtedly provide fertile ground for cultural memory studies for decades to come. Also, the continued development of Africa, Asia, and the Middle East will likely involve reassessing the past and the creation and transmission of cultural memory. The wide-spread use of the internet potentially provides a new platform representing cultural memory. E-mails, blogs, and videos posted by various groups on YouTube could prove to be key representations of cultural memories for scholars in the future.

Curating Archaeological Artifacts

Alex W. Barker

Museum of Art and Archaeology, University of Missouri, Columbia, Missouri, U.S.A.

Abstract

Archaeological artifacts, collections, and associated records represent arguably the most important resource for documenting the entirety of the human career. Their integrity and value, however, depend on appropriate management and curation. This entry provides a brief survey of standards and generally accepted practices for the documentation, acquisition, cataloging, care, use, and interpretation of curated archaeological collections as well as a summary of metadata standards and current ethical issues confronting archaeological curators.

INTRODUCTION

Archaeological collections represent a primary form of cultural heritage and one of the major sources of evidence regarding the human career. The value and integrity of these collections depends on appropriate curation, management, and care; this entry briefly summarizes key curatorial concerns, and addresses current trends and ethical issues relating to curatorial practice in archaeology.

Various definitions have been offered, but for our purposes, archaeology (the spelling with “ae” is generally preferred, but some U.S. federal sources prefer the spelling “archeology,” and some scholars in classical archaeology continue to use the diphthong “æ”) may be defined as the study of human behavior from its material correlates and physical residues. This definition places material objects—and information relating to these objects—at the center of archaeology as a scholarly enterprise. This emphasis on materiality need not limit the kinds of questions archaeologists address, but does frame the nature of the evidence on which archaeological research is based. Technically, at least, archaeologists do not actually study the past. Instead they study evidence of all kinds that has survived from the past into the present or from the present that may be more broadly applicable, in order to make inferences about the past. More than a fine distinction, this fact informs most guidelines regarding the proper management and curation of archaeological collections.

Archaeological sites are fragile, finite, and non-renewable resources. Rates of site loss and looting are alarming. The trade in antiquities is difficult to quantify, with estimates ranging from \$300 million to more than \$6 billion annually.^[1] While rates of site loss and destruction are equally difficult to quantify, Heritage Action in the United Kingdom has estimated that between 1975 and 2015 more than 12,268,252 artifacts have been removed from sites in England and Wales alone by metal detectorists,^[2] and Elizabeth Stone, a specialist in the

archaeology of southern Iraq, has documented looting activities in southern Iraq between 2003 and 2007, larger in areal extent than all archaeological excavations ever conducted in the region combined. More recent research by Brodie and Contreras used Google Earth to identify looted areas at a single site in Jordan totaling more than 74,000 m².^[3]

While new archaeological sites are being created constantly by living societies, those from any past period or society are both limited in number and subject to destruction or damage from a wide range of natural and human-induced processes. Even the act of archaeological excavation is inherently destructive, and hence archaeologists focus much attention on preserving, in situ, undisturbed archaeological material and in maximizing the information that may be gained from artifacts, collections, or samples already excavated. Most professional archaeological organizations have explicit, and all have implicit, ethical frameworks requiring that archaeologists work to minimize damage to the archaeological record.^[4] Most archaeologists view that obligation as relating primarily to the preservation of intact sites or cultural resources, but equally important is the preservation of collections resulting from past research, and the maintenance of information relating to those collections that gives them meaning and significance. Properly curated, older collections can continually address new questions and be examined using new instrumentation and methods.^[5]

CURATING ARCHAEOLOGICAL ARTIFACTS

The number of archaeological objects held in the world’s museums and repositories is unknown, but the scale is enormous. Individual sites may produce tens of thousands of discrete, uniquely cataloged artifacts or objects, and the number of already-recorded sites is considerable, with an unknown number yet to be discovered. Japan has already

recorded more than 440,000 archaeological sites within its borders, Denmark's *Kulturhistoriske Centralregister* has recorded more than 150,000 archaeological sites, with a schedule of 55,000 monuments (not including buildings), and New Mexico, USA, currently lists more than 100,000 recorded sites in its automated ARMS site registration system.^[6] The U.S. Department of the Interior estimates its 2014 holdings at more than 44.9 million objects,^[7] and this includes neither associated archival records (more than 122 million items relating to all scholarly disciplines, with the proportion dedicated to archaeology as yet unknown) nor major holdings administered by other arms of the federal government (e.g., the Department of Defense through, among others, the U.S. Army Corps of Engineers, or the Department of Agriculture through the U.S. Forest Service).

STANDARDS

Currently there are few standards for the curation of archaeological collections, and no generally recognized standard for the recording or interchange of information regarding archaeological collections. The irony of this situation is that archaeology has been concerned since its inception with creating order and meaning from the complex and often jumbled remains of the past that survive to the present day. In order to do so, archaeology depends upon *context*, the spatial, cultural, environmental, and temporal associations between objects. Probably the most important form of context is *provenience*, or the physical context in which an object was found. Objects without provenience have limited archaeological value, and many archaeological journals prohibit the first publication of such materials. These prohibitions reflect two concerns: (1) that validating objects recovered from looted or unknown contexts may lead to further site destruction and (2) that the inclusion of objects from unknown contexts may introduce either fakes or misattributed items into the scholarly literature in ways difficult to later remedy, biasing interpretations and creating false foundations on which later scholarship relies. Provenience, etymologically from the same root, generally refers to the chain of custody and goodness of title for objects or collections. The terms are sometimes confused, particularly by scholars in different disciplines that emphasize one concept at the expense of the other: Art historians privileging provenance will sometimes treat provenience as a subset of provenance; archaeologists privileging provenience will sometimes treat provenance as a special, postexcavation case of provenience. Both concepts are crucial for managing archaeological collections, with provenience being central to the utility of objects in making archaeological inferences and provenance being central to assessing claims for restitution, repatriation, and return of objects.

Probably the most broadly applied standard for managing archaeological collections in the United States is a set of federal regulations that govern the management of federally owned or administered archaeological materials, 36CFR79,^[8] promulgated in 1990. They mandate levels of intellectual, environmental, and physical control over collections and related documentation, but for the most part these levels of control aren't clearly specified but instead must minimally correspond to changing professional standards within museums. In the United Kingdom the equivalent, and in most respects more detailed, set of guidelines is *Standards in the Museum Care of Collections: Archaeological Collections* originally prepared by the Museums & Galleries Commission.^[9]

PROJECT DESIGN AND RECORDS

Management and curation of archaeological collections actually begins prior to fieldwork. The design of field projects plays a major role in determining the long-term research value of archaeological collections. Since archaeological collections include not only artifacts and other cultural material but also a range of environmental and lithostratigraphic materials, potentially including the soils, sediments, or matrix within which objects were recovered, all collections ultimately reflect sampling. Sampling in this sense assumes at least two forms: (1) sampling strategies determining which areas are surveyed, studied, or excavated and (2) recovery strategies determining what kinds of materials and samples are retained from those areas sampled. Since the absence of certain categories of material in a curated collection may represent either their absence from in situ deposits or a field decision not to collect those classes of material, documentation of the research design and data recovery plan is critical for understanding the material record.^[10]

All archaeological projects generate collections, although in some cases the collections comprise only documents, photographs and records. Different kinds of survey or excavation projects employ a variety of techniques for recording the horizontal and vertical locations as well as the associations of objects, samples or measurements; this information is linked to objects by recording contextual information on the artifact, on the bag or other container housing the object or objects, or by assigning objects or groups of objects from the same context a lot number keyed to contextual information in project records, as well as by paper or electronic field notes and forms. Records also document how objects were consolidated or cleaned in the field, if applicable. Often, objects are assigned field numbers that link the object to its context and associated records; this represents a preliminary labeling system separate from identifiers used by the museum or repository.

ACQUISITIONS AND ACCESSIONS

Objects being considered for acquisition by an institution are generally examined relative to formal acquisition policies defining the kinds of material held by that institution. In some cases this is framed by the interests of the staff or stakeholders, in others by formal collecting plans or acquisition policies, and in others by the institution's mission statement or by legal mandate (e.g., governmental repositories). These policies also specify who within an organization has the authority to accept objects and who has authority or responsibility for different aspects of the acquisition process and subsequent management of the collection, and specify the conditions under which objects are accepted.^[11] Usually, institutions will not acquire objects for which they cannot receive good title, which they do not expect to retain, or for which they cannot provide adequate care (although in some cases institutions may accession objects for which nominal title is retained by the government). For museums and repositories, at least, ultimate authority for acquisitions rests with the governing authority, as it is legally responsible for the institution's actions.

If objects are determined to be appropriate for acquisition, the next step is *accessioning*, which establishes legal custody and ownership of objects or collections, and documents the means by which an institution acquired the material. Depending on what kinds of information accompany the collection, it may also be the first step in establishing intellectual control over the material. While procedures vary widely, each accession generally represents one or more objects, including a whole collection from an archaeological project, from a single source, acquired by a single means of acquisition or transfer of title, and accepted on a single date. Accessioning establishes custody and title for one or more objects and is usually distinct from *cataloging*, which identifies each individual object and provides descriptive detail based on curatorial expertise. In larger institutions, at least, the registrar records accessions while the curators catalog objects. Some recording systems treat the accession and catalog number as identical, others use separate catalog and accession numbers, and some employ a hybrid system in which parts of the same numeric sequence convey accession and catalog information. Usually accession and/or catalog numbers are written on or affixed to the object. In some large museums the accession and catalog numbers are affixed to objects as barcodes or electronic tags, changing the mechanics of the registration process but not its underlying logic.

CATALOGING

Cataloging requires the identification and classification of an object and reflects the professional expertise and background of the curator. A variety of descriptive schemes

and terminologies may be employed, and different archaeologists may employ differing cultural–historical frameworks, functional typologies, or nomenclatural standards.

Multiple standards for collections documentation have been proposed, and even institutions adopting one or another standard often modify the standard to better suit their individual needs. Probably the most widespread is the CIDOC International Core Standard for Archaeological Objects, developed by the Archaeological Sites Working group of the International Committee for Documentation (CIDOC) through the International Council of Museums.^[12] For the most part, such standards define the kinds of information to be recorded, but not the terminology or classificatory frameworks to be employed. For the United Kingdom, Collections Trust UK provides an excellent outline of the registration and documentation process, along with links to resources for terminologies or lexicons for archaeological objects.^[13] While useful for a given region, such resources are not for the most part transportable to other regions without substantial modification. Commonly employed terminologies include the Nomenclature for Museum Cataloguing (a revision of the Chenhall system)^[14] and the Getty's Art and Architecture Thesaurus,^[15] although neither is considered fully satisfactory by most archaeological curators. As there is no accepted standard within the discipline, the choice of terminology or lexicon is in some respects less critical than the consistent application of whatever set of terms is adopted, particularly now that most collections cataloging involves the creation of electronic records that facilitate synonymies and the cross-indexing of terms. Consistency benefits search and retrieval within an institution, and supports emerging efforts to allow searches across the collections data of multiple institutions.

Cataloging also involves identifying whence objects come. In addition to intrasite provenience information, it is also necessary to uniquely identify the site and geographic location from which objects originate. Unique site designations are normally provided by governmental agencies or ministries (in the United States by the state historic preservation officer or state archaeologist), but geographic names require some external authority or lexicon. Commonly used geographic authorities include the Geographic Names Information System for the United States and the Getty Thesaurus of Geographic Names for global place names.

METADATA STANDARDS

Metadata, or data about data, documenting the structure, format, and content of data fields or information, represents a crucial concern in establishing accessible and meaningful intellectual control over collections. Metadata standards in archaeology have not yet achieved their initial promise of allowing relatively source-transparent

searches across multiple datasets. In part, this reflects the proliferation of metadata standards, and in part, a paucity of systematic application of existing standards. Most archaeological metadata is built on the Dublin Core, an ANSI (Z39.85-2001) and ISO (15836) approved standard widely used for resource recovery, with extensions to handle data of particular concern to archaeologists (see also ISO 21127, the ISO implementation of the CIDOC Conceptual Reference Model (CRM), which relates specifically to cultural heritage information).^[16] In theory the Dublin Core represents the basal data used by a variety of disciplines, with discipline-specific extensions developed to meet the needs of specific communities of users. In practice the Dublin Core is generally mapped on to a subset of existing datasets that correspond to the Dublin Core elements. CIDOC, for example, provides mapping of the Dublin Core elements to the CIDOC CRM. The Darwin Core, a metadata standard paralleling the Dublin Core but aimed primarily at natural history and systematics or biological taxonomic collections, emphasizes georeferencing of objects rather than standardized place names.^[17] In theory such metadata allow collaborations, gateways, and interoperable search platforms, but this promise has yet to be realized. For the most part, such searches remain limited to within either individual data archives such as The Digital Archaeological Record (DAR) or the Chaco Research Archive^[18] or within archaeological data publishing initiatives such as Open Context or the Comparative Archaeology Database (CADB).^[19]

STORAGE AND CARE

Once cataloged, the curator and/or collections manager becomes responsible for the storage and care of the object. The logic by which storage areas are organized varies by institution, and may be based on catalog number, geographical area, or type of object. Certain classes of objects may be stored together because they share a need for specific environmental profiles (e.g., low relative humidity) or to reflect sensitivities of key stakeholders (e.g., human remains being stored separately from other collections). The creation and maintenance of appropriate storage conditions is a complex process of monitoring and controlling (or ameliorating) a variety of environmental parameters, while providing appropriate levels of physical security and access to the collections.^[20]

There is, unfortunately, no ideal temperature or humidity for all objects; each kind of material has separate ideal environmental conditions, and in the case of compound or complex artifacts there may be contradictory ideal conditions for the constituent materials making up a single object. A hafted axe comprising a wooden handle, sinew lashings, organic glues or mastics, and a metal bit might be stored at low humidity to protect the metal from corrosion, but at the expense of the wood. Conversely, higher

humidity might maintain the dimensional stability of more hygroscopic materials like wood, but at the expense of the metal. And the ultimate goal is not merely preserving the constituent materials but the integrity of the artifact as a whole, and the ways they are combined to form that complex artifact.

For the most part, however, constancy in environments is crucial, and shorter-term variations in environment are more damaging than longer-term changes.^[21] For museum collections absolute humidity is less relevant than relative humidity, since hygroscopic materials are affected by whether their ambient environments have little moisture relative to their capacity to hold moisture, in which case they absorb moisture from objects, or are nearer their maximum capacity for moisture, in which case they tend to release moisture into objects. This capacity is, in part, a function of temperature. From the standpoint of dimensional stability and direct damage, most objects are less sensitive to temperature changes than to humidity, although temperature and humidity are generally linked, and both natural processes of decay and the likelihood of pest infestations are accelerated at higher temperatures. Temperature and humidity levels are generally monitored using either analog thermohygrographs or multichannel digital data loggers. Other sources of environmental damage are airborne particulates and light, especially in the high-energy ultraviolet wavelengths. Light damage is cumulative, and bright lights for shorter durations do not generally cause greater damage than longer exposure to dim lights. Light levels are generally controlled by limiting the foot-candles of light to which objects are exposed, both by moderating lighting in display areas and by storing collections in closed cabinets, by sealing windows and by using ultraviolet filters on all light sources. Light levels are normally measured with a direct-reading UV light meter or less accurately with a visible light meter that estimates UV levels.

Pests are another threat to the integrity of collections and associated documentation; one (probably apocryphal) story from the American midcontinent describes rodents eating the labels off every bag from an entire archaeological field season, leaving the bags intact but with no record of their source or contents. Insects, particularly dermestid beetles, are also a significant and persistent threat to organic materials. Prevention is the preferred approach; most chemical treatments generally cause as many problems as they solve.^[22] For insects, thermal treatment (freezing either at very low temperature or for a period longer than the life cycle of the pest) is a commonly employed treatment strategy, and anoxic environments can be used in some cases. In the past, a variety of hazardous materials including arsenic, strychnine, and mercury were used to treat for pests and to prevent mold or mildew; these treatments have resulted in some older collections now being classed as biohazards requiring special storage, handling, and disposal protocols. Treatments of any kind,

whether to control for pests or to conserve and stabilize objects should be documented as part of the permanent record as they may inform subsequent management decisions or influence analytical testing.

Objects are also subject to physical damage, and a series of protocols on handling objects are available, varying in detail but similar in general form and practice.^[23] Padding and supports for objects may be needed and can be constructed from nonacidic closed-cell foam or similar conservation-grade materials; all materials, containers, and cabinets should be inert and nonacidic.

In recent years, many institutions have adopted care policies that incorporate the concerns of descendant communities. The Museum of Indian Arts and Culture in Santa Fe, New Mexico, does not fully seal cases containing kachina dolls to allow them to “breathe,” the Milwaukee Public Museum allows certain objects to be wrapped and bundled with tobacco or other ritually potent plants, and the storage facilities for the National Museum of the American Indian, part of the Smithsonian Institution, include a smoking room for the blessing of material objects by native groups. Such policies often require a compromise between museological and traditional approaches to care, and if adopted should be developed in close consultation with appropriate communities.

The physical security of collections should generally be provided by an overlapping combination of physical security (e.g., locks), electronic security (e.g., alarms or cameras), and human security (e.g., either guards or supervision by collections staff), although the degree of physical security is often contingent on both the available resources and the perceived level of threat.

ACCESS AND USE

Along with stewardship, one of the primary obligations of curators is to provide access to the collections for scholars and interested individuals or groups.^[24] Stewardship and access require a balance, however, as increasing levels of access put objects at increasing levels of risk of all kinds. The movement and handling of objects increases the risk of physical damage, theft, variation in microenvironments, accumulated light damage, infestation, and generally increased wear and tear on objects. But at the same time, increased use adds to the value and intellectual potential of objects; since archaeological collections include both objects and their associated information, research adds to the collection by increasing the information associated with objects, and by clarifying the relations between objects. Access to collections is also crucial for consultation with descendant communities or other stakeholders with specific links to collections, as well as allowing opportunities for traditional forms of care including purification rites. Collections may also be loaned for study or other appropriate purposes. Past practice allowed a wide

range of loan conditions, but more recent practice generally requires that loans be for a period of 1 year or less (although loans may be annually renewable) and that the borrower be an institution rather than an individual comply with all conditions set by the lending institution, and provide a standard facility report to ensure that appropriate storage conditions can be provided. For research loans, most institutions require a copy of resulting publications or studies, and most museums and repositories loan only to institutions. Policies governing appropriate access, use, and loans should be listed in collections management policies or other documents approved by the institution’s governing authority. As both usage of the web and acceptance of applicable metadata standards increases, access policies will need to address web-based access and attendant issues of fair use and copyright.

INTERPRETATION

One of the primary differences between museums and repositories is that museums have an explicit educational and interpretive mandate. As a result, curators may be involved in a range of exhibitions and interpretive programs. Exhibition or program design and museum-based informal science education are separate fields, each with their own journals, infrastructure, training, and guidelines for professional practice. Curators generally serve as content experts as part of design teams, although in smaller institutions curators may be asked to simultaneously serve in all of these roles. Programmatic use of collections must balance the preservation and protection of the objects and documents against the mission-defined value of public understanding and instruction. While allowing visitors to confront and be engaged by authentic objects is an important role of museums, in many programmatic contexts replicas may be equally effective as ancient artifacts and constitute a more appropriate option.

Museums play an important role in influencing how the public perceives cultures both extant and extinct, and potentially in reifying or rectifying stereotypical or naïve assumptions about past lifeways.^[25] Interpreting the past is a complex enterprise, however, in which perceptions are an amalgam formed from at least three complex constellations of elements: (1) the past itself; (2) the viewpoints, attitudes, and assumptions of the curator selecting and interpreting the representations of the past; and (3) the viewpoints, attitudes, and assumptions of the visitor.^[26] The ways in which these elements relate to one another is better documented than understood, and because the curator occupies a privileged position in influencing the ways in which the past is represented—and thus the ways in which the past intrudes into and influences the present—he or she must be particularly sensitive to the ways that their own biases and agendas influence the selection of objects, topics, and the narratives through which the past

is presented and represented. Curators influence representations both by the objects or topics they select and by those they do not, as well as by how effectively they communicate concepts and information to visitors with different backgrounds, interests, and preferred learning modalities. Archaeological objects may be easier to present and interpret for visual learners, for example, whereas auditory and kinetic/tactile learners may face additional challenges in apprehending the core messages a given exhibition seeks to communicate.

In the past, exhibitions or programs were often designed as vehicles for curators to showcase artifacts and refine public sensibilities. Current best practices in museums call for program design beginning with a clearly defined set of take-home messages and with the didactic, pedagogical, and aesthetic design of the subsequent exhibition or program crafted specifically to communicate and reinforce these messages. Evaluation of the effectiveness of selected strategies is often necessary and usually results in both an iterative process of correcting weaknesses in the initial program design and ultimately in more robust and effective programs. Exhibit design thus includes not only aesthetic and pedagogical dimensions, but significant logistical, political, social, and ethical dimensions as well.

ETHICAL ISSUES

Curators of archaeological collections face a number of other ethical dilemmas. Some are common to all disciplines—making hard choices between competing needs or priorities in the face of limited resources, or choosing among optimal environments for storing complex artifacts made of multiple materials, each with a different optimal environment. Others are unique to archaeology, with five being worthy of mention here: (1) the so-called curation crisis; (2) orphaned collections; (3) deaccessioning and disposition of archaeological objects; (4) looting and the acceptance of unprovenienced antiquities; and (5) repatriation and restitution of objects or collections.

The enormous scale of archaeological collections worldwide is not mirrored in the availability of resources to maintain and properly curate them, nor to protect and document unrecorded or unexcavated sites. This has resulted in a “curation crisis,” in which an increasing number of museums and repositories lack adequate space or staff to care for new collections irrespective of their importance or value, while others process new collections at the expense of bringing older collections up to acceptable standards of care and curation.^[27] As stewards of cultural heritage, archaeological curators must assess whether they and the institution they represent can afford collections the necessary levels of care to ensure their integrity and security for years to come, and to meet new standards over time.

Not all archaeological collections are housed in institutions providing permanent care and support of objects. Many academic institutions generate significant archaeological collections over the professional lives of individual faculty members, but in many instances there is no mechanism in place to ensure adequate curation after the retirement or death of an individual. In other cases, institutions holding collections, but not viewing curation as central to their mission, decide at some point that the costs of curation are unacceptably high, or the unit caring for collections is disbanded due to the vagaries of institutional funding or vision. All result in “orphaned” collections carrying with them not only the logistical and facility costs to institutions willing to offer them a permanent home, but also significant curatorial staff time to bring them to acceptable standards.^[28] Recognizing this problem, some granting agencies and academic departments are requiring that curation arrangements be included in cultural resource project and academic research designs alike, and that necessary costs be included in project budgets.

All artifacts are not equally valuable in documenting the human past, and many scholars feel that only a portion of certain kinds of mass-produced or commonly encountered objects need to be preserved. Bricks from a historic site may reveal significant manufacturing and architectural information, but it is questionable whether every brick needs to be curated in perpetuity. Similarly, fire-cracked rock from prehistoric sites, or certain categories of undecorated body sherds from sites producing millions of such sherds in large-scale excavations, may reveal information that can be preserved from subsets of the mass of material encountered within a site. In some instances these issues are addressed through the project data recovery plan, which determines what kinds and quantities of objects are transferred to the museum or repository. In other cases, the issues must be addressed by the collecting institution, either by initially accepting only parts of a larger collection—in which case the status and future of the remaining parts of the collection are at best uncertain—or by selectively removing objects later in time. The pitfall of such removal is that innovative scholarship and future technical capabilities may transform categories of objects currently of little analytical or scholarly value into crucial pieces of evidence and accurately scrying the future is difficult for most students of the past.

Deaccessioning is the formal process by which an institution removes an object or objects from its collection. Most institutions have formal processes for deaccessioning requiring review and approval from multiple levels of authority—often more rigorous than those required to accession an object—and specific restrictions on the disposition of objects once deaccessioned. Many museums have policies allowing the sale of deaccessioned objects if the proceeds are used exclusively to acquire other objects for the collection (both as an ethical practice and because within the United States, museums are able to

treat collections as nonfinancial assets excluded from capitalization if such practices are followed),^[29] but the sale of antiquities is viewed as problematic by many within the discipline. In most cases, transfers to or exchanges with another peer institution are preferred methods of disposition. British museums have traditionally resisted deaccessioning of material, and in many parts of the world deaccessioning requires approval from appropriate governmental agencies or ministries. Within the United States, there are currently (July 2015) no guidelines under 36 CFR Part 79 to allow federal agencies or museums to deaccession and dispose of collections deemed of insufficient archaeological significance to warrant the continuation of permanent curation, although draft deaccessioning rules have been proposed by the National Park Service on multiple occasions.

Objects from looted contexts or otherwise lacking provenience generally have limited value for systematic research, but may nevertheless be works of considerable aesthetic or cultural merit. And in some instances, inherent qualities of the object may confer considerable scholarly importance on objects despite their uncertain pedigree. Site destruction in Iraq from 2003 to 2008 uncovered large numbers of cuneiform tablets whose contents have remarkable epigraphic and historical significance even if their original context cannot be reliably determined. Most archaeological organizations counsel against work with unprovenienced objects and forbid the first publication either of such objects or of research based on them, but this means that much information may be lost first through the loss of archaeological provenience, then again from loss of what information the resulting artifacts might offer. Some scholars find it difficult to reconcile that loss of information with their ethical obligations of stewardship, and question whether the validation of such finds by scholarly study will really increase rates of site destruction and looting, or further commercialize antiquities.^[30] Such questions admit to no easy answers, although most professional organizations eschew unprovenienced objects for another reason as well—in the absence of detailed provenience data, it is easy for fakes or misattributed objects to mislead the unwary and jeopardize the integrity of future work based upon the shaky foundations offered by unprovenienced antiquities. Some institutions—primarily a few larger art museums—have expressed little concern for whether or not an object is from looted contexts or even whether their purchase of such objects may spur further looting. In their view, the aesthetic merit of the object outweighs both its questionable pedigree and the consequences resulting from its acquisition. Such approaches are generally condemned by scholarly and professional organizations as unethical and inappropriate.

While accessioning of collections involves an assertion of title by the museum, title actually represents a bundle of rights that have increasingly unraveled in past decades. Under the provisions of the Native American Graves

Protection and Repatriation Act of 1990 (NAGPRA), recognized tribes and native corporations may claim objects from museums if they fall within one of four defined categories: (1) human remains; (2) associated and unassociated funerary objects; (3) sacred objects; and (4) objects of cultural patrimony.^[31] While museums may have held custody of these objects for a century or more, NAGPRA specified that museums did not receive good title to these objects because they were either inalienable or communally owned, and hence not subject to transfer of title by any individual. While NAGPRA has led to the return of many items from museums and repositories, it has also increased communication between repositories and native tribes, and spurred cooperative agreements between museums and descendant communities.

Claims by nation-states for objects looted from sites within their statutory boundaries have also increased in recent years, in part due to more aggressive cultural patrimony policies in source countries and the increased role of antiquities in nationalist ideologies and in part due to evolving legal standards for the applicability of the National Stolen Property Act (NSPA) of 1934 (as amended) to looted antiquities.^[32] Under the so-called McClain doctrine (based on the 1979 case *United States v McClain*), foreign governments may invoke the NSPA if the objects were looted after the passage of an unambiguous and generally enforced cultural patrimony law in the country of origin vesting ownership of all antiquities in the state. Prior to this, the legal standing of either individuals or governments relative to unprovenienced artifacts was unclear, as in the absence of provenience information the harmed party having standing to bring suit was difficult or impossible to establish. While these details are specific to the United States, similar problems can be cited from most other developed nations; Britain continues to wrestle with Greece's demand for the return of the Elgin marbles, France with the return of a range of ethnographic objects to Native peoples, and Germany with claims for the return of the Amarna bust of Nefertiti to Egypt.

CONCLUSION

One reason that archaeological collections are the object of such contention is that they are building blocks for national and community identities, constructs that are themselves used to construct charters for present beliefs and legitimization of ideologies through the authority that rooting them in long-standing tradition confers. "The past is full of life, eager to irritate us, provoke and insult us, tempt us to destroy or repaint it," the Czech novelist Milan Kundera once wrote, adding "the only reason people want to be masters of the future is to change the past. They are fighting for access to the laboratories where photographs are retouched and biographies and histories rewritten."^[33] Archaeological collections remain the clearest and most

immediate record of worldwide cultural achievement and social change over the broad sweep of the human career. The legal, ethical, and procedural outlook of curators of archaeological collections has changed significantly over the last decade, and there is little reason to believe that the decades to come will be any less dynamic and demanding for the stewards of the past.

ACKNOWLEDGMENTS

I am grateful to Lana Coggeshall and Terry Childs for reading drafts of this entry and for their constructive criticisms. I am also indebted to members of the Museums, Collections and Curation Committee of the Society for American Archaeology (SAA), the SAA Ethics Committee, the Ethics Committee of the American Anthropological Association, and the AAM Ethics Task Force on Cultural Property for many productive discussions of the topics included here and to the *ELIS* editors and anonymous reviewers for their helpful comments.

Curating Natural History Collections

Kimberly S. Bostwick

Ecology and Evolutionary Biology, Cornell University Museum of Vertebrates, Ithaca, New York, U.S.A.

Abstract

Natural history collections are composed of objects of natural origin, most often of biological or mineral nature. These collections include organismal collections (like plant, insect, and animal collections) as well as anthropological and geological collections. Curating such collections requires establishing the longevity of the objects while maintaining their scientific utility. Maximum scientific utility is ensured by preserving with as little modification as possible the object, protecting the object against degradative processes, and managing the object information in an unambiguous and easy-to-retrieve way. While many specialists may be involved in curating larger, more active natural history collections, smaller collections are often managed by only one or two people. The goal of most natural history collections is to create and maintain a scientifically-useful research resource. The uses to which collections are put include educational, artistic, and scientific purposes. Several specific examples are given of how specimens have been used as unique informational resources for scientific research.

INTRODUCTION

The term “Natural History” refers to the study of all things natural, especially as it relates to the history of our planet and the lifestyles, features, and habits of animals and other organisms living on it. Natural history collections are those containing objects meant to assist natural historians, geologists, anthropologists, and biologists determine patterns through time. For the biologist this includes determining what species exist, where they existed, what their form is, and to the extent indicated by their form, what their habits are. For the geologist this might include describing the material composition of naturally-produced mineralized or earthen bodies, such as rocks or continents, and how these have been formed and changed through time.

Natural history collections include collections of natural, as opposed to manmade, objects. Typical objects in organismal collections include the bodies, body parts, or natural products thereof, of once living individuals. These individuals may be of literally any living species of plant or animal and are more often referred to as “specimens” (Fig. 1). Most natural history collections specialize in one natural, evolutionary group of organisms, or another, called taxa. Thus, we have herbaria, specializing in plant taxa, entomological collections specializing in insect taxa, vertebrate collections specializing in vertebrate taxa (such as birds, mammals, reptiles, fish), etc. Different taxa lend themselves to different subjects of study and different methods of research, and this, coupled with the sheer numbers of species, necessitates professional specialization on some subset of living creatures, and explains the reason for natural history collection specialization.

Anthropological collections are a special type of organismal collection because the objects contained in these collections are often only from one or relatively few species (humans, or recent prehuman primate species), and often include significant holdings of nonbody objects (such as tools, clothes, or pottery).

Another common deviation from the rule of taxonomic specialization are paleontological collections, which tend to include diverse groups of organisms from many different taxa (i.e., plants, insects, invertebrates, and vertebrates), but which are united by their fossilized form. The mineralized form determines the kind of research that can be done on fossils, and the preservational needs of the objects in the collection. Thus, paleontology’s departure from other natural history collections is caused by practical considerations—fossilized objects have shared physical features, and therefore break off naturally as objects with similar management needs.

Despite primarily being defined by the kinds of their objects, natural history collections also tend to have shared missions, goals, management needs, professionals, and activities. The mission in particular is somewhat distinctive from that of other types of collections. The mission of natural history collections is to ensure the long-term persistence of data-rich specimens specifically to facilitate future scientific studies. Given that the ultimate goal of natural history collections is to support the “current and anticipated needs of biological and/or geological science,” the standard activities, and practices conducted in these collections may change through time as different technologies become available, and different scientific questions become of interest.

The orientation toward repeatable science also leads to the critical importance of data associated with natural

history specimens. Since most natural history research involves fine-scaled measurement and placement of objects geographically or temporally, when and where an object was collected is critical contextual information, and is critical for the utility of a given specimen for most scientific studies. In the end, nearly as much time can be spent gathering and managing the data associated with physical specimens as is spent acquiring and managing the specimens themselves.

The following discussion is broken into three sections, each designed to add complementary perspective on what natural history collection are and how they function. The first part describes natural history collections from the perspective of bringing a new object into the collection and following it through the various activities involved in formally incorporating it into the collection. Part II views collections from a more human, managerial point of view, considering who works in collections and what their respective roles are. Finally, Part III reviews a small series of published scientific studies that together demonstrate how natural history collections are used to contribute to our understanding of the natural world. These examples hopefully serve to emphasize how science guides the fundamental principles behind the development and maintenance of natural history collections.

These discussions are structured around my experience curating organismal, specifically vertebrate, collections. However, it is important to acknowledge that different types of collection have their own specific traditions, needs, and practices.

CURATING COLLECTIONS I: THE SPECIMEN POINT OF VIEW

Below we explore the multifaceted activities that comprise curating a natural history collection. One of the most

tangible ways to understand what is involved in curating natural history collections is to follow a specimen through the process of collection, identification, preparation (the preliminary act of preservation), accession, cataloging, installation, long-term conservation, monitoring, and preservation, as well as administration of a specimen for use.

Collecting and Preparing

The “specimen” to which natural history curators constantly refer is typically the body, or body part, of an individual (Fig. 2). Occasionally, it may be a product of an individual (such as a bird’s nest), the product of a group of individuals (such as a bees’ nest), or be multi-individual (such as a clutch of eggs or a colonial organism), or any of a number of other, nonorganic, natural objects (crystals and rocks, for instance). For the purposes of this discussion we will imagine the body of a single individual organism.

The methods used to collect individuals depend on the type of organism. Collecting may involve simply picking or digging the individual up (as in fossils, plants, or some insects), or trapping (insects, fish, reptiles), netting (fish, birds, and bats), shooting (birds and mammals), or

Fig. 2 A natural history collection’s type specimen. These three images are from one individual alcohol-preserved *Synodontis acanthoperca*, CU 89005 (this new species of catfish has no common name).

salvaging (finding dead) the specimen. Collecting is done to minimize damage to the specimen, and to maximize data collected with the specimen. Data can include: (1) minimally, when and where the specimen was collected; (2) the immediate habitat and social environment the specimen was collected in; and (3) any potentially relevant information that is present at the time of collection that will not be ascertainable from the specimen directly later on. The color of living tissues is a good example of a feature that often changes shortly after death, and is often impractical or impossible to preserve. Audio or video recordings, photographs, or notes can capture this associated specimen data.

For some organisms, preparation can happen at the time of collection (plants, insects, fish), in other organisms preparation may be labor intensive, in which case it is more efficient to separate the process of collection from the process of preparation.

For any given taxa, several “preparation types” are possible. Dry-preserved and fluid-preserved preparations are the most common. The basic principle behind dry preservation techniques is facilitating dehydration of the internal parts of the organism to retain the appearance of the external features. Thus, plant specimens can be dried to preserve vegetative patterns. Animal specimens may need to have their internal parts removed before being dried to preserve the exoskeleton, skin, and fur or feathers. Drying prevents bacteria-driven rot or decay, and hinders molding, which allows the external features—often already dry—to remain unmodified and available for study (Fig. 3).

Alternatively, specimens can be preserved in fluid. Fluid preparations prevent decay either by “fixing” or chemically altering the tissue so that it is un-degradable by bacteria (i.e., formalin fixation), or, again, by dehydrating the specimen by removing the water while still keeping it in fluid (alcohol preservation, usually ethanol or isopropanol). These preparations are ideal for

organisms with moist or thin skins (fish, reptiles and amphibians, and many aquatic invertebrates) and have the added benefit of keeping the internal organs, tissues, and structures intact. Fluid preservations often compromise the external appearance by wetting structures (feathers and fur) and colors of integument are often lost or modified.

The primary goal of all preparation techniques is to establish the longevity of the specimen and specific targeted features (determined by the method of preservation). Further efforts are made to standardize as much as possible the posture or shape of the individual to maximize information retrieval and ease of storage, and minimize likelihood of handling damage. Care is taken to minimize physical and chemical manipulation of the specimen with the goal of reducing the risk of removing or destroying potentially useful information.

Accessioning, Cataloging, and Installing

Once a specimen has been prepared, the next phase of curation is the management and long-term preservation of the collection objects and their data. Accessioning is the first step in the formal admittance of the specimen to the collection. Accessioning is a paper or computer-based process whereby a group of specimens entering the collection are recognized as a group united by their origin. The origin of the specimens may be as official as a collecting event or expedition in which a group of people travel to a specific place to collect a set of specimens, or as informal as the contents of a wildlife rehabilitator’s freezer. Each accession is given a unique identifier, and correspondences, contact information, any associated specimen data, any applicable permits, etc. are held in a folder for each accession.

Determination, or identification and characterization, of a specimen is attempted before cataloging. In some cases this is a trivially easy task, as specimens coming into collections are often representatives of common and/or

Fig. 3 Dry specimens with external features preserved. Here four *Euplectes ardens* specimens from the Cornell University Museum of Vertebrates are seen as they are in the collection, with plumage and external morphology available for study.

Source: Photo courtesy of Kim Bostwick, Cornell University Museum of Vertebrates.

easy to identify species. However, in some cases, especially in non-vertebrate groups of animals, determining the species identity of a specimen can be difficult, time consuming, and/or impossible. In these cases, the collectors and/or collection staff do their best to make as exact an identification as possible. Redeterminations can be done later when more information is available, or when an expert in a given group is available to examine the specimens.

Cataloging each of the individual specimens in an accession is the next step and achieves multiple critical functions. It results in the assignment of a unique, institution and collection-specific identifier (often a number) that will be used to identify the specimen for the rest of its term in the collection. Cataloging also results in the capture and standardization of the specimen data in a way that allows rapid and efficient generation of labels, reports, loan forms, etc. for any future activity related to that specimen. Once cataloged, a specimen may finally be considered a “curated” specimen of the collection.

Once cataloged, the specimen is ready to be installed into the collection itself. Collections are organized by species, with more closely related species being located near one another, or alternatively, alphabetically by species names according to major taxonomic groups. Within species, specimens are usually organized according to subspecies, and/or geographic locality of the specimen, and/or date information (Fig. 3). The practical reason for arrangement by species is size/preparation uniformity, and the nature of human inquiry that often seeks direct comparison of closely related things.

Long-Term Care: Housing and Monitoring

Once installed into the collection, specimen curation involves protecting the specimens from the degradative effects of their environments. Long-term care starts with the housing circumstances of the specimens. The building and rooms where the specimens are housed are literally and figuratively the building blocks upon which good curation rests. Ideally, the building will be designed or chosen as the first line of defense to protect the collections from light, water, excessive humidity and temperature fluctuations, and pests (usually insect, fungal, or rodent). This usually amounts to a tightly enclosed space with few windows, physically barricaded from any noncollection spaces (such as offices or hallways), with environmental controls.

Of perhaps equal or greater concern than the rooms in which specimens are housed, is the museum cabinetry or furniture into which specimens are placed. This furniture is chosen to further mitigate the same destructive forces the room is; light, humidity fluctuation, and pests, and to additionally protect from airborne dust particles and physical damage from exposure. Thus, in the case of dry specimens, cabinetry is sealed tightly against dermestid beetles

(a family of carpet beetles). In the case of fluid specimens, the specimens are housed in jars filled to their sealed tops with alcohol.

Inside cases, the materials directly surrounding the specimens are also critically important: buffered papers, archival ink, and inert building materials are used to minimize specimen deterioration. Acidic and basic materials can chemically alter the sensitive organic compounds of most organisms and are generally avoided.

Once a stable environment is established, from the materials touching the specimen most immediately, through to the rooms housing the collection, the last curatorial task is monitoring. Routine examination of specimens is required to ensure that the protective measures have not been compromised and to keep chaotic forces from reducing the high level of order that a specimen collection represents into disarray and deterioration.

Administering the Use of Specimens

Natural history collections exist to be used, and often use is the single greatest source of damage to collections. Thus, the goal of longevity and the mission of supporting research and education must be balanced.

Use has become more and more about using the data associated with the collections. Information requests use the data gathered in the database, and are strengthened by having specimens to “voucher,” or verify by proxy, their legitimacy.

Other uses involve the direct examination of specimens for research. Some research aspires to describe patterns of diversity, and simply involves examining specimens visually, or with simple measuring devices such as calipers, spectrophotometers, etc. Other research requires “destructive sampling.” In these cases use of the specimen involves a procedure that will irreversibly alter the specimen. This may be dissection of a fluid-preserved specimen, or a subsampling of tissues, such as skin or feathers. For destructive sampling, the value of the specimen as determined by its uniqueness or commonness, or overall physical or data quality, is weighted against the value or significance of the use (research vs. teaching), and against how destructive the procedure will be. Severely destructive sampling of a valuable specimen requires a more stringent justification than minor sampling of a common or data-less specimen. Whether or not to allow destructive sampling is a judgment usually made on a case-by-case basis by the collection’s curator.

Data and Database Management

Increasingly, database management has become an important part of specimen curation. Individual collections manage their own data using either off-the-shelf generic database software or software customized for use by natural history collections. These databases allow the creation

of electronic collection management tools for creating reports, labels, and for answering specimen queries quickly and efficiently. Collections can also make their specimen data, or some subset of it, available over the internet for general queries regarding collection holdings or data associated with specimens. Several initiatives are allowing the federation of collections data from numerous institutions. This allows the specimen data from multiple institutions to be searchable from a single portal, and mapping tools are increasingly being used to visualize geographic ranges using data from the collective natural history collection's holdings.

CURATING COLLECTIONS II: THE ADMINISTRATIVE POINT OF VIEW

Another useful way to break down these and other activities related to curating natural history collections is to consider each of the professionals, amateurs, and students who complete the tasks described above. The discussion that follows describes one commonly conceived division of the titles and divisions of responsibilities used in natural history collections (that most familiar to me), but it is important to be aware that other institutions may have different titles for the same roles, or a different breakdown of how duties are divided and shared. Nonetheless, natural history collections may have any of a number of the following people associated with them: curators, collection managers, collectors, preparators, archivists, conservators, student assistants, and volunteers. Alternatively, curation may be done by one or very few people. Either way, between them, these people strive ensure the above described curatorial activities are being done, and being done well.

Curator

Given that natural history collections are developed as a resource for scientists, the highest administrative role within a natural history collection is held by the curator. The curator is most often a scientist who uses specimens in his or her own research, has experience in scientific collections, and also has a broad and deep knowledge about the diversity and biology of the taxa held in the collection he or she is responsible for. Because the practice of science changes so rapidly, a curator must be in touch with how specimens are likely to be used, and a practicing scientist is in the best position for maintaining the appropriate perspective for guiding curatorial decisions and practices.

Like all professionals in natural history collections, the curator typically performs many activities. These can be organized into several sets of tasks. I here consider these as fulfilling each of 4 roles, that of: (1) a professional

“taxologist”; (2) a practicing scientist; (3) an educator; and (4) an administrator.

In the role of the taxologist, the curator acts as the knowledgeable specialist about the various biological features and diversity of the group of plants or animals in the collection curated. As such, he or she is best equipped to strategize about collections growth, selecting the species and specimens of greatest interest for addition to the collection. The curator's active place in the larger scientific community allows him or her the social and opportunity-driven resources to “acquire” such specimens. Once acquired, judgment for “identifying” and “organizing” the specimens using the most up to date information is critical.

As a practicing scientist the curator has a unique perspective on what specimen features are important to preserve to maintain a specimen's scientific usefulness. For instance, in Ornithology, the depth of the bill is a common measure oftentimes used to distinguish among species or populations of birds. Thus, the curator will make sure newly trained preparators pay special attention to make the correct alignment of the mandibles and ensure complete closure of the mouth during specimen preparation.

The educational and administrative roles of a curator involve less direct interaction with the collections themselves. In their educational roles, curators often give talks or seminars, guide tours, or otherwise host activities meant to promote not only knowledge in different biological areas but also the value of collections themselves. This may or may not involve the production of exhibits.

In addition to overseeing the other members of the curatorial team, one of the primarily administrative ways in which a curator curates his or her natural history collection may be through grant writing and planning to enhance the environment the specimens are housed in, or expand the collections themselves. This can include everything from reorganization of the collection according to modern ideas about organismal relationships, to the purchase of new specimen cabinetry, to planning new collection building solutions, or the funding and arrangement of a major collecting expedition.

Finally, the last major administrative contribution of the curator is the negotiation of the terms of use of specimens. Keeping in mind that the mission of the collection is to serve science, and use always entails the risk of specimen damage, immediate and future use needs must be balanced by judging potential specimen damage or consumption against scientific merit of a given project, and the rarity or uniqueness of the specimen in question.

Collection Manager

The Collection Manager is the central figure in the day-to-day and hands-on aspects of the collections. His or her duties include technical, for lack of a better word “custodial,” managerial, and educational roles.

On a daily basis a collection manager will be accessioning specimens, preparing them, cataloging them for installation into the collection, and/or overseeing student or volunteer assistants completing these activities. He or she will also be monitoring and ordering curatorial materials necessary for running the collection.

The collection manager has a suite of more irregular duties as well. For instance, collecting tends to occur in sporadic bouts, since it must be conducted outside the office and usually requires some planning. There are meta-specimen responsibilities as well such as making sure the collection labels are accurate, and also verifying the long-term protective measures being taken, in the collection are effective. The collection manager usually removes specimens from the collections to display for visiting classes, or to fill out and mail the loans approved by the curator.

Finally, one major and increasingly complex role assumed by the collection manager is the management of the various permits needed to maintain a functional collection and to allow legal collection and transport of the plants and/or animals of interest. Depending on the types of organisms held in the collection, this may indeed be a significant sink of time and energy.

Specialists: Collectors, Preparators, Archivists, and Conservators

Occasionally individuals are associated with natural history collections whose sole role is to collect and prepare new specimens for addition to the collection. These are often loose arrangements or affiliations of mutual benefit to the collecting/preparing individuals and the institution in which they deposit their materials. The donating individuals get an institutional affiliation, and the recipient collection gets new specimens for little cost. This arrangement was more common historically when large-scale collecting was more commonplace and full-time collecting was a viable profession.

Additionally, some larger museums, when they house many individual natural history collections, hire professional archivists or conservators whose job it is to research the practices and materials used within collections. Their goal is to make knowledge-based recommendations that will increase the longevity of the collection's specimens.

Assistants: Students, Interns, and Volunteers

Much of the work involved with curating collections is interesting and, with a little training, entirely doable by novices. This means that student trainees, interns, and volunteers can and do contribute significantly to the hands-on work done to curate natural history collections. From typing and printing labels, to preparing, installing, and even cataloging specimens, these collections assistants often account for a significant proportion of the

curatorial man-hours required to maintain a well-curated natural history collection.

CURATING COLLECTIONS III: USES, SIGNIFICANCE, AND VALUE

As time has passed the primary uses, significance, and value of natural history collections has expanded. In some cases, collections are still working tirelessly on the original goals of natural history collections; documenting the diversity of species on the planet, where they live, and what they look like. For instance, Fig. 2 shows the “holotype,” or the original species-name-bearing individual of *Synodontis acanthoperca* on which the species' original description was wholly or partially based. Botanical and invertebrate collections in particular still occupy this unique, critical role in the foundation-building tasks of alpha taxonomic descriptions and inventories.

In all organismal natural history collections now—including the relatively more well-known vertebrate groups, like birds and mammals—data and specimens are being used in new ways for ecological and evolutionary studies asking new kinds of questions. Below is a small set of published scientific studies using, in this case, bird skins, in nontraditional ways. These examples illustrate new uses of natural history collection specimens.

Using Specimens for Research: Documenting Changes in . . . Reproductive Physiology

When Peregrine Falcons' numbers were crashing in the 1950s, there were anecdotal observations of crushed eggs being found in nests, but it was difficult to know the significance of these observations. In 1968, a paper was published in *Science* describing the results of a study comparing the eggshell widths of 1729 birds' eggs.^[1] The eggs, held in 39 different natural history collections, were collected across nearly 80 years of time, from six different species from all over the United States. For 57 years, the average weight and shell width of Peregrine Falcons in California were constant, then, between 1947 and 1952, eggshell weights dropped precipitously by 18.9%. Similar patterns were found in Osprey eggs, Bald Eagle eggs, and Peregrines from other parts of the United States. Where Peregrines had already been extirpated in the East, egg shells “had become” up to 26% thinner. Documentation of this dramatic change, and being able to pin it down to a very specific time period, was critical in pinning down the cause of the problem; the use of chlorinated hydrocarbons like DDT became widespread in the United States in 1946. This study became a classic example of how natural history specimens could contribute to our understanding of how animals were changing, and why.

Population Structure

A recent study of the federally endangered Marbled Murrelet used a method called age-ratio analysis to determine how the proportion of juvenile to adult birds varied from year to year.^[2] Juveniles have different plumages from adults, and analysis of 170 Marbled Murrelet specimens collected off the coast of California between 1892 and 1922 indicated proportionally more young birds than adults. This information allowed inference of what the rates of reproduction and adult survivorship were around the turn of the century. The researchers discovered that the rates of adult survivorship are the same now as they were then. However, the rates of reproduction have dropped eight to nine fold; the relative number of young individuals have decreased dramatically in these birds, and this is likely responsible for the declining populations of Marbled Murrelets.

Trophic Level of a Predator

The relative proportion of Carbon and Nitrogen isotopes in feathers can tell us about what a bird was eating at the time it was growing its feathers, and therefore how “high” it feeds on the food chain. Another study on Marbled Murrelets using isotopes extracted from the feathers of museum specimens has shown that historically, young Murrelets were able to exist as higher-level predators in their environments then they can now.^[3] Now they appear to be subsisting more on smaller prey items than on the sardine fishes they used to flourish on, before overfishing caused dramatic declines in sardine and other small fishes.

Symmetry and Ecological Stress

In animals where the right and left sides are mirror images of each other, like ourselves, high levels of symmetry are achieved and maintained throughout development. However, in more stressful developmental circumstances, we are more likely to have small deviations from perfect symmetry. In this way, one might determine if a group of animals is “stressed” by carefully measuring the degree of symmetry of its individuals. One study compared the lengths of the right and left leg bones in 133 specimens of six species of birds collected in an unbroken, undisturbed forest in Kenya between 1934 and 1948, with the same species netted and measured in the same forest plots in 1996–1998, after the forest had become highly fragmented and degraded. The contemporary birds in the most degraded plots of forest were four to seven times less symmetrical than their 1940s counterparts from museums, indicating although the species were still surviving in these forests, they may well be living life on “the edge.”^[4]

Genetic Diversity

A suite of studies have been published using DNA extracted from the toes of natural history specimens to determine the genetic diversity of bird populations decades ago and compare them with populations today.^[5,6] Prairie Chickens in particular have been the subjects of studies that have shown allelic diversity is dropping in these populations, approaching levels reached by Heath Hens prior to their extinction.^[7] These studies have further shown that genetic studies of modern populations alone cannot always accurately infer historical levels of diversity.^[8]

Ecological Niche during Speciation

Not all studies of natural history specimens focus on changes being wrought by man and occurring in the last century. Insight to far more general processes, such as speciation, can be obtained from specimens as well. This is highlighted in a study where museum specimen data for mammals, birds, and butterflies was used to examine sister-species pairs for patterns of similarity.^[9] “Sister species” are species who are each other’s closest relatives. As each other’s closest relatives, sister species tell us something about what changed when speciation happened. One model of speciation suggests that species become adapted to different environments and that is what causes or drives speciation. If this is true, we would expect the habitats of sister species to be demonstrably different in some ecological factor. Using sophisticated artificial intelligence algorithms, with detailed mapping of environmental parameters and massive amounts of specimen data drawn from multiple natural history collections, scientists were able to show that most often, sister species lived in environments that were completely co-habitable to one another, with no sign of ecological separation. Using this result they concluded in many circumstances it is simply vicariance—or being physically separated by a barrier for some period of time—and nonadaptive forces that drive speciation in many species.

CONCLUSIONS

Natural history collections are as diverse as the natural objects curated in them, but share the function and goal of advancing scientific research. The curatorial traditions and practices within any given collection are determined by the nature of the objects curated, and guided by the research questions likely to be asked. A diversity of professionals can share the various curatorial duties, or in the case of small or less-active collections, a single person may aspire to manage the collections. In any case, the value of collections’ objects tend to increase with time as they become increasingly rare vouchers of individuals from places and times that have changed or ceased to exist.

The examples discussed in Part III serve to highlight the diversity of ways in which even one type of collection (bird dry skins) are being used for science. Any type of natural history collection could generate an equal list of diverse and important scientific uses. It is worth noting that for most of these studies, the specimens used were collected decades before DNA, or stable isotopes, fluctuating asymmetry, etc., were discovered as research tools, and decades before pesticides or habitat changes like overfishing existed to have their effects studied. Thus, no framework for asking the questions answered in these studies existed at the time the specimens were collected. This highlights the unique value of natural history collections as archives of information, and this in turn guides the principles and practices therein.

Custody and Chain of Custody

Bernadette G. Callery

School of Information Sciences, University of Pittsburgh, Pittsburgh, Pennsylvania, U.S.A.

Abstract

Custody, the holding of records and objects in archives and museums for security and preservation reasons, has been a fundamental principle of collections management in those institutions. Having an unbroken chain of custody, that is, being able to accurately identify all the individuals and organizations that have owned these items since they were created, has been considered as an essential evidence of the authenticity of the object and supports the legality of its transfer from one owner to the next. However, legal custody does not necessarily imply legal ownership. In the late twentieth century, the usefulness of custody as a management principle has been challenged in museums by repatriation claims and in archival collections by replevin and the need to both preserve the authenticity and integrity of electronic records and to guarantee access to both paper and electronic records over time.

INTRODUCTION

Custody, the act of holding archival records and museum artifacts for purposes of preservation and security, has long been an important principle in the collection management practices of both archives and museums. Traditional definitions of custody combine physical possession with the assumption of appropriate care of those collections. Having custody of an object also implies controlling access to it. Public museums and archives typically operate under the mandate that their collections are held in trust for the public good. The rationale for maintaining such public collections of objects and documents is to preserve the authentic evidence of the cultural and artistic diversity of human endeavor and to protect those materials from damage or loss. Access to these collections is considered a public benefit, an attitude that museum historians trace to the Enlightenment. However, in some collections, preservation and access can be seen as mutually incompatible goals, as even careful handling can place fragile materials at risk. Such tensions can result in restricted access, although such restrictions can also be based on other considerations, such as the terms of the donor agreement or institutional policy on access to intellectually rather than physically sensitive materials.

With the increasing professionalism of museums and archives, codes of ethics have been developed that support standard practices of collection, acquisition, preservation, and interpretation. Awareness of these codes of ethics and their application in collections holding cultural heritage materials is critical to a consideration of custody as they reflect changing attitudes toward their validity of claims to cultural property, particularly that owned by indigenous, colonized, or conquered peoples. Writing on this change of focus, Brown notes that prior to the late 1980s “museum curators, archivists, and anthropologists had

rarely worried about whether the information they collected and managed should be treated as someone else’s property.”^[1]

One widely cited ethics code that deals with the acquisition and care of collections is that of the International Council of Museums (ICOM), which notes that “Museums that maintain collections hold them in trust for the benefit of society and its development.” The commentary on this ethical standard specifically states that collections should not be acquired without an assurance of valid title or otherwise illegally acquired. Section 2.3 additionally establishes the value of securing and maintaining provenance information, noting that “Due diligence in this regard should establish the full history of the item from discovery or production.”^[2]

The ICOM Code of Ethics additionally identifies international legislation designed to protect cultural heritage materials, including the 1970 United Nations Educational, Scientific and Cultural Organization (UNESCO) Convention on the Means of Prohibiting and Preventing the Illicit Import, Export, and Transfer of Ownership of Cultural Property. With over 100 signatories, this legislation and its associated national implementations, such as the U.S. Convention on Cultural Property Implementation Act of 1983, form the basis for the international control of import restrictions of cultural objects. While much of the international legislation related to establishing ownership and custody of collections brought into museums and archives deals with art objects, natural history collections are also covered by the Convention on International Trade in Endangered Species of Wild Fauna and Flora (CITES), passed in 1973 and implemented in the United States through the U.S. Endangered Species Act. CITES protects species threatened by international trade by requiring permits issued by the source country for the export of CITES-listed species.

Within the museum community, provenance research documents an object's chain of custody, accounting for the complete history of ownership of the object prior to its arrival at the museum. Anthropological collections use the term *provenience* to define the object's specific geographic location of origin; natural history collections use the term *locality* to identify the specific geographic location where the organism was collected. Documentation can take the form of field notes, photographs, site plans, collection permits, correspondence with donors and dealers, bills of sale or deeds of gift or conservation notes, all of which may be housed separately from the objects, often in the institution's archives or registrar's files. Within the archival community, the term *provenance*, or the *respect des fonds*, refers to the principle that records of different origins are to be kept separate in order to preserve their different contexts.

Once in the custody of the museum, it was assumed that the object would be protected against any further undocumented alteration or damage. The goal of museum provenance research was to identify those previous owners and confirm the circumstances of the transfer of ownership.

In many cases, identification of that sequence of owners substantiates the identity of the object itself, by locating it in specific historical times and places. A study of an object's provenance can also be used to invalidate the claims of a museum's ownership of the item, if sufficient evidence can be found to indicate that the object was obtained illegally. Since the 1998 report of the Association of Art Museum Directors Task Force on the Spoliation of Art during the Nazi Era, modern art museum provenance research has been primarily focused on the restitution of artworks confiscated during the Nazi Era (1933–1945).^[3] This interest in provenance research, with its emphasis on identifying gaps in the chain of custody or items that have passed through the hands of “red-flag” dealers, those who were known to have been in collusion with the Nazis, has resulted in an increase of publicly available information about the provenance of artworks. Many museums have contributed extensive provenance information to the collaborative Nazi-Era Provenance Internet Portal Project sponsored by the American Association of Museums.^[4]

The validity of American museums' stewardship of objects of cultural patrimony of Native Americans was addressed by the 1990 U.S. law, the Native American Graves Protection and Repatriation Act (NAGPRA). The purpose of this act was to protect Indian burial sites from further looting and provides a legal mechanism by which descendants of culturally affiliated tribes could request the return of human remains and sacred objects from the collections of federally funded U.S. museums. The ongoing debate has focused on the potential loss of access to these objects for scientific study versus the return of illegally obtained objects, many considered sacred or communal

property and therefore not transferable outside the tribe. However, the number of objects actually repatriated has been less than what critics of the law feared, with many tribes choosing to leave these objects in the custody of the museums, although sometimes imposing more specific requirements on their storage, limiting public access to these objects, and restricting their use in exhibitions.^[5]

CUSTODIAL HISTORY AND POST-CUSTODIAL APPROACHES

Donors to both archives and museums often believe that their contributions will be maintained in perpetuity under controlled circumstances, reinforcing the assumption that such custody confers lasting value on the object or collection of documents. The term “museum quality” implies that these specific items are recognized as highly representative, particularly fine examples, or otherwise worthy of special distinction and care because of their association with notable individuals or organizations. In the archives community, the term *custodial history* is used to describe the record of the list of successive organizations or individuals who have held these materials since their creation and can refer to both physical and intellectual possession. Institutional archives, including governmental records, are those records identified as having lasting value to provide accountability for the organization's actions toward the community it serves or for evidence of the business process or transactions, but are not in active use by the creators of the records. The practice of moving these records from the creating offices into the archives frees space for the records documenting current activities, and assures the safety and continuing availability of those materials designated as archival by protecting them against damage and unconsidered dispersal. Historical theories of custody in archives are based on the writings of European and British archivists responsible for limited numbers of decentralized governmental records dealing with land ownership and taxation based on property rights. However, with an increasing quantity of the business processes of organizations created and maintained electronically, a post-custodial theory of archives has emerged.

Recognizing the ephemeral nature of electronic records, post-custodial archivists believe that they cannot wait for the deposit of the records as delivered by the creating agency, but must be proactive, becoming involved with the agency from the earliest stages of records creation, ideally even before the record is created, in order to advise on which records are to be maintained permanently and to determine how best to capture the context in which the records were created and used. Solutions posed by the post-custodialists include leaving the records identified as having archival value in the offices and computer systems of the creating agencies rather than transferring them into the separate physical custody of the

archives. The significant difference of post-custodial theory is that the responsibility of the archivist is imbedded in the ongoing management of the records of the organization rather than being an external custodian of records housed in a centralized repository to which they are delivered by the creator. Opponents to this distributed custody approach argue that this practice is counter to the traditional responsibilities of archivists and could lead to unauthorized removal or alteration of the records. Supporters of this approach state that it is impossible to maintain electronic records outside of the social and software context of the creating business practice. Post-custodial theories of archives management require a more proactive involvement of archivists in the design of information systems and their deployment and maintenance through institutional retention policies.

In these professions in which the term custody is employed, there is an expectation that objects held in custody will be protected and preserved for the common good, but not necessarily owned by the museum or archives. The lack of physicality of electronic records presents additional preservation concerns as well as the ongoing management of intellectual property.

CUSTODY AS APPLIED TO MUSEUMS

Museums often refer to their responsibility for objects in their collection as stewardship, which implies the preventative care of custody as well as the responsibility for holding the materials in trust for the public good. The American Association of Museum's 2000 Code of Ethics contains the following statement on the acquisition and retention of collections.

The distinctive character of museum ethics derives from the ownership, care, and use of objects, specimens, and living collections representing the world's natural and cultural common wealth. This stewardship of collections entails the highest public trust and carries with it the presumption of rightful ownership, permanence, care, documentation, accessibility, and responsible disposal.^[6]

The apparent permanence of the museum's custody contributes significantly to the public trust in museums. This trust can be undermined by a lack of public understanding of the process of deaccessioning, when a museum chooses to reverse its original decision to accept an object into its permanent collection. While refinements are made in a museum's collecting policy, as well as the inability of individual museums to adequately care for certain types of collections do present legitimate reasons to deaccession items, the process of deaccessioning often provokes negative public comment, which can damage the museum's position as an organization deserving of the public trust. Removal of an object from the museum's custody is seen

as devaluing that object and, by association, the donor.^[7] Some commentators identify the increase in media and public concern about museum deaccessioning practices, beginning with the highly publicized deaccessions from the Metropolitan Museum in New York in the 1970s, with an increased demand for "access to records documenting the history of ownership of museum collections [which] also grew as the right of museums to continue to have custody over certain objects was challenged."^[8]

Ideally, the legal status of the transfer of ownership and its implications for the legality of ownership are documented in carefully written and retained donor agreements and accession records. While museum curators, directors, and boards may be involved in the acquisition of museum objects and subsequently generate records pertaining to that transaction, those records are typically maintained by the museum's registrar.^[9] As these records may be added to, and amended over, the lifetime of the object in the museum and may even outlast the object itself, these collection records are considered continuously current and often remain in curatorial or departmental offices rather than being removed to the separate custody and control of the museum's archives.

CHALLENGES TO CUSTODY IN MUSEUMS: REPATRIATION REQUESTS

In the United States in the late twentieth century, a growing number of Native Americans had been approaching museums, requesting the removal of objects of cultural significance and human remains from museum exhibitions and research collections and petitioning for the return of these materials to the custody of the associated tribes. Many of these materials were collected a century earlier in the belief that these tribal communities were in decline and would require an accelerated mode of collecting similar to that of salvage archaeology in which extreme measures are taken to collect in bulk when a cultural landscape is in immediate danger of destruction. The apparent need for speed, the market value of these objects of material culture, and the lingering belief that these indigenous peoples were uncivilized and primitive led to abuses that further threatened the continuation of these communities. Passed in 1990, the NAGPRA covers all U.S. museums receiving federal funds, with the Smithsonian Institution's United States National Museum of the American Indian covered under an equivalent legislation, the 1989 National Museum of the American Indian Act. The highly structured process of repatriation mandated by NAGPRA, which puts the burden of discovering documentation on the holding museum rather than the claimants, recognizes that legal custody does not necessarily imply legal ownership. While the law was intended to provide for the repatriation of material acquired by museums in the recent past, the most contested application of the law was the

disposition of the skeleton discovered in Kennewick, Washington, in 1996, now dated to be over 9000 years old. A number of local tribes claimed the skeleton for reburial, stating that they were descendants of tribes that had occupied the area in the past, and were countered by a group of anthropologists and archaeologists who wished to maintain the skeleton's availability for continued scientific study.^[10,11]

While there is a formal process of U.S. law governing the return of human remains and sacred objects to the tribal descendants, there are not similarly clear or well-defined laws addressing the return of antiquities, even when there is strong evidence that they had been illegally acquired. Arguments that the preservation of cultural treasures taken as the spoils of war was better handled by the conquering nation date back to the Napoleonic campaigns, although many of the objects exhibited in the Louvre were returned to the countries from which they were despoiled under the terms of the 1815 Congress of Vienna. The international agreement that forms the basis for modern repatriation requests of objects of cultural patrimony is the 1970 UNESCO Convention on the Means of Prohibiting and Preventing the Illicit Import, Export, and Transfer of Ownership of Cultural Property.^[12]

Demands for the return of the "Elgin Marbles," marble sculptures removed from the Parthenon in Athens, Greece, between 1799 and 1803 by Thomas Bruce, seventh earl of Elgin while he was the British ambassador to Constantinople and then sold to the British Museum in 1816, are the most highly publicized of these international museum custody battles. Preservation was one of the justifications for the removal of these artifacts from their original locations and Elgin's removal of these sculptural elements can be seen as an early example of salvage archaeology. Although Elgin had paid for the privilege of removing the sculpture through negotiations with the local Ottoman occupying force, popular outcry addressing the cultural dislocation began almost immediately with their arrival in London with satirical references in several poems by English poet Lord Byron.

While the number of claims for the return of cultural property is increasing, particularly in the area of antiquities, some have been resolved to the satisfaction of the claimants, such as the return of such objects as the Euphronios Krater. Negotiations were concluded in 2006 for the Metropolitan Museum's return of this sixth century BC bowl signed by the Greek painter Euphronios to the Republic of Italy in 2008 as part of its cultural heritage. As noted in a recent overview of cultural property laws, "The debate is over not only who owns the past, but in whose hands the stewardship of cultural heritage should lie."^[13] Some archaeologists claim that more restrictive import and export laws will make the black market less profitable and stem the tide of cultural heritage items from artifact-rich but resource-poor nations.

CUSTODY AS APPLIED TO ARCHIVES

Historical theories of custody in archives are based on the writings of European and British archivists responsible for decentralized governmental records dealing with land ownership and taxation based on property rights. Both the 1898 publication of a practical manual on the care of archives by three Dutch archivists and the 1922 *Manual of Archive Administration* by British archivist Hilary Jenkinson address the difficulties of maintaining the authenticity of archival collections accumulated in a number of locations without a formally documented transfer of custody. Jenkinson worked his entire professional career in the Public Records Office in London, the repository for governmental records extending back into the medieval period, and established for the purpose of centralizing British governmental records. Jenkinson "connected authenticity with continuous custody of archives by their creator and its legitimate successors. The argument is that the creating body has an interest in preserving its records free from any tampering that would affect their authenticity, of being what they seem to be."^[14]

In his 1954 *Modern Archives: Principles and Techniques*, based on his experience in the United States National Archives, American archivist Theodore Schellenberg rejected the concept of continuous custody required by Jenkinson on the basis of the complexity of the process of the production of modern records and the impracticability of guaranteeing an unbroken line of continuous custody when records were produced by a number of different divisions of an organization in different locations. Nonetheless, Schellenberg believed that once records had crossed the threshold of the archives, they needed to stay in the custody of the archives in order to guarantee their integrity following their arrival.

With the proliferation of paper records and the technological complexity of electronic records, American archivist F. Gerald Ham recommended a post-custodial approach in his 1981 "Archival Strategies for the Post-Custodial Era," in which the archivist's role was less than that of a keeper concerned with the physical custody of records and more a proactive manager of records, taking on advisory responsibilities toward the creators of records. Both Canadian and Australian archivists have explored various aspects of post-custodial theories as applied to the records of business and government, wanting to assure both access and accountability for local records of government and business.

Physical custody of electronic records is a meaningless concept without the maintenance of the supporting environment of software and business practice, hence the development of a theory of distributed custody, in which records may remain with the creating agency, but with guidance provided by archivists as to their disposition and long-term maintenance. Various post-custodial

theories providing solutions to the problems of custody of archival records in electronic form include distributed custody, or leaving those records in the hands of their creators, with the archives providing guidance on their management and serving as a last resort.^[15] (For an extended discussion of how the inter-relation of custody and access was applied to the archival records of the Virgin Islands.)^[16] New skills for the archivists now include digital curation, which requires that archivists take responsibility for maintaining both the context and content of digital information, focusing “not just on preserving digital entities but on keeping them functional, supporting their continuous annotation and maintaining their fitness for purpose.”^[17]

Control of records, regardless of their form, is a means of protecting them and the basis for assurances of continuing authenticity. Post-custodial approaches do not mean a noncustodial approach. Archivists administering records held in distributed custody would continue to “guarantee the long-term preservation of ongoing social, cultural, historical, or symbolic value.”^[18]

CHALLENGES TO CUSTODY IN ARCHIVES: REPLEVIN REQUESTS

Although issues of contested custody in museums are more immediately newsworthy, particularly when they involve looted art or antiquities of dubious provenance, there are equivalent cases in archives that are no less significant. Two cases can be used to illustrate the use of replevin as a technique to challenge an archive’s custody of documents. Replevin is defined in the Society of American Archivists’ online *Glossary of Archival and Records Terminology* as “an action to recover property that has been improperly or illegally taken” and notes that it is a technique frequently employed to describe efforts to recover public records that are in private hands.

In December of 1955, a suit was brought against the Minnesota Historical Society contesting the ownership of a previously unknown collection of field notes compiled by William Clark substantiating details of the events of the Lewis and Clark Expedition between December 1803 and April 1805. In addition to the family in whose possession the documents had been discovered, the claimants in the suit included the United States, based on the notion that Thomas Jefferson, who had initiated the expedition, had requested that the records of the expedition be submitted to the government. However, historically, the federal government had not previously claimed any of the other Lewis and Clark expedition papers, many of which were held in private and public collections, or indeed any records of government-sponsored expeditions. There was considerable opposition to this, particularly from those collections, who were concerned that “the government’s claim to Clark’s ‘Field Notes’ posed a threat to any

privately owned historical documents.”^[19] The court ruled in October 1955 that the government could not sustain the burden of proof in establishing its claim; therefore, the field notes were private papers rather than public documents. Following the ruling, the family sold them to a private collector, who in turn donated them to Yale University. A scholarly edition of the papers, *The Field Notes of Captain William Clark, 1803–1805*, edited with an introduction and notes by E.S. Osgood, was published in 1964. This edition includes facsimiles of the original pages, allaying the fears that the information in the papers would become unavailable, if the papers had gone into a private collection.

A replevin case in which the reverse ruling was made in an appeal was the 1975–1977 case of the legal briefs dated 1767 and 1768 signed by William Hooper of North Carolina, considered to be one of the rarest of the 56 signers of the Declaration of Independence. Shortly after these items had been offered for sale by autograph collector B.C. West, he was informed that “the state of North Carolina claimed his two Hoopers on the grounds that title to any paper that had once been a public record remains with the state.”^[20] A 1977 ruling on the ownership of the Hooper documents granted custody of those documents to the state of North Carolina. While much discussed at the time, particularly by manuscript collectors, this case did not set a precedent for replevin and similar state documents were offered at subsequent public auctions and not requested by the state. Nonetheless, organizations such as the Manuscript Society have issued policies on the custody of abandoned or discarded government documents which support the rights of individual rights of ownership when the person can demonstrate legal title. This debate continues in the United States over the ownership and accessibility of presidential papers.

Another case of contested custody in archival collections deals with the acquisition of the Stanton Glantz Research Files of the Brown and Williamson Tobacco Corporation, established at the University of California, San Francisco, Library and Center for Knowledge Management in 1994, which provided public access to copies of internal documents from the tobacco company’s files which had been given anonymously to Glantz, a cardiologist and tobacco-control activist at the University of California, San Francisco (UCSF). This collection, the basis for the research in the 1996 publication, *The Cigarette Papers*, was the subject of a lawsuit in which the Brown and Williamson Tobacco Corporation sought to remove the material from the University of California library that indicated that the tobacco industry had suppressed research on tobacco addiction and its health risks. The ruling of the San Francisco Superior Court allowed the release of the documents on the Internet, stating, “the public has the right to know.”^[21,22]

That government offices, particularly at times of political unrest, are not the most reliable of stewards has been

proven so again and again, in such cases as the South African Truth and Reconciliation Commission, established in 1995, to investigate the destruction of records created during the period of apartheid.^[23] Similar efforts in Argentina, Brazil, Chile, El Salvador and Guatemala have attempted to gain access to public records dealing with the rights of individuals under previous regimes. The release of previously secret files such as those maintained by the Stasi, the Ministerium für Staatssicherheit, the official secret police of East Germany raises questions as to the potential for social and personal harm caused by the availability of these records.

CONCLUSION

Museums and archives have traditionally taken custody of cultural objects and records of lasting value as a means of fulfilling their obligation to preserve the past for the future. In both types of institutions, contextual information is required in order to give meaning to the objects, including maintaining and enhancing information on the identity and use of the items as well as information on the circumstances of their acquisition through ongoing scholarship and exhibitions. Modern theories of cultural property have challenged the retention of some cultural items by these institutions, most notably NAGPRA, the U.S. law passed in 1990. The application of this legislation has resulted in the repatriation of many objects of cultural patrimony to those identified as lineal descendants. Additional legislation such as the CITES controls the transportation of animals and plants across international borders in order to help protect endangered species and their often equally endangered habitats. Provenance research applied to the return of works of art looted during the Nazi Era heightened social responsibility as chronicled in Lynn Nicholas, *The Rape of Europa: The Fate of Europe's Treasures in the Third Reich and the Second World War*, New York: A.A. Knopf, 1994. Although successful claims have been made for the return of antiquities from museums to the current governments of the original creators, these repatriations have not gone uncontested. Some critics argue that such actions will diminish the research collections held in modern museums, which exist to provide a critical mass of cultural material for valid comparative scholarship.

Parallel to the reasoning that museums give value to objects selected for their collections, some archival theorists argue that records held in the custody of archives retain their authenticity which would not be the case if they were left in the hands of their creators. Critics of this approach argue that the records may well have been tampered with prior to their deposit in the archives and therefore may not represent the full truth of business transactions. Post-custodial theories of archival management have been developed to deal with the custody of

governmental and business electronic records which require maintaining a surrounding environment of software and business practice.

Determining the custody of an object or document is an essential responsibility of museums and archives. Responsible stewards of collections should begin by determining the deceptively simple fact of ownership of collections under their care.

Abstract

This entry presents a definition of data and their quality dimensions as the basis for a survey of data quality management and improvement techniques, with special attention to data published on the Internet. Several factors have contributed to making improved data quality an urgent priority. These factors include “data quality disasters” such as the Year 2000 Presidential Election, corporate reporting, and homeland security, and the stunning growth in data volumes, and recognition of the importance of data to the modern organization. This entry does not treat issues of database system quality, such as system reliability, accessibility, and usability, or related issues such as data security.

THE NATURE OF DATA

Of the triumvirate of concepts *data*, *information*, and *knowledge* at the conceptual foundations of the information age, data is by consensus regarded as the most basic. Like the other two, however, the concept of data is not well understood. Although it is basic, the notion of data is surprisingly multifaceted and complex. One reason for this is that the word is used in so many different ways in conversation. For example, one hears comments such as the following:

1. The data on this graph prove my point.
2. The data point is six.
3. See, here are the data we need.
4. I cannot get the data out of the database.
5. When you get some data like that, you know it is time to do something drastic.
6. The data misled us because they were wrong.

Some of these uses of the word treat data as tangible measurements, as in comments 1 and 2. In other uses, the term seems less tangible, but is a motivator for action, as in comments 3 and 5. Some uses seem to treat data as something abstract or conceptual, as in comment 2, and others seem to deal more with physical representations for data, as in comments 1 and 4. In some cases data are treated as factual, and in others, like comment 6, the data may not be correct. This variety of uses of the word data raises many questions about what data are, and how we should understand the term.

A thorough treatment of data quality must be based on a clear understanding of the meaning of the term data. In

developing this understanding in this section, we first explore the data life-cycle, the sequence of phases through which data pass as they progress from creation to storage and use. Data’s life-cycle model is, in effect, a formal way of looking at “the social life of information.”^[1] The life-cycle model helps account for the different uses of the term data because, at different stages in their life, data change in subtle ways. Based on the lifecycle, we consider definitions of data and select the definition that encompasses the most critical features and advances our objective of quality assessment, control, and improvement.

The Data Life Cycle

As noted, the data life cycle is the sequence of activities that create and populate a *data bank* in which data are stored, find and extract data from a data bank, and manipulate and use extracted data (Fig. 1).^[2] The data life cycle includes the following activities:

1. *Defining a model*—The portion of the real world to be described by the data is defined, and the detailed mechanism of description is specified. This involves defining entity types, their attributes, and attribute domains, all discussed further below.
2. *Implementing the model*—An empty data bank, or physical data repository, is created. In a small organization, the data bank may be a sheet of paper, and implementing the model may involve laying out columns for recording data. For electronic databases, the model must be described in the language of the database management system.

Fig. 1 The data life cycle. (© Navesink Consulting Group.)

3. *Obtaining values*—Data values are collected for the part of the world modeled in the data bank. Common ways of obtaining data values are measuring, surveying, observing, and copying another source. Poor data values are a principal issue in data quality and are discussed throughout this entry.
4. *Storing values*—Data values are recorded in the data bank according to the conventions established in the data model.

The result of these *data acquisition* activities is data stored in a data bank. Subsequent *data usage* activities put the data to use in the following ways.

5. *Define a view*—Typically a data customer or application requires only a subset of the data available in a database. A *view* describes the portion of the data to be used. By convention, in quality management, we call those who use data, products, or services *customers*. Technologists often refer to the same people as *users*.
6. *Retrieve*—Data (values) of interest are retrieved from the data bank.
7. *Manipulate*—Data are processed in one or more of four principal ways: classification, analysis, manipulation, and synthesis. This step is sometimes bypassed when the sole intention is to present data to a customer.
8. *Present results*—The data are formatted (graphed, listed, etc.) and given to the customer. The appropriate form of presentation depends on many factors, including the results of retrieval and presentation, the presentation medium, and the customer. (People need one form of presentation, application software, another.)
9. *Use*—Data may be used on presentation to the customer.

This simplified version of the model does not include activities to access the quality of data and make adjustments. (The reader interested in such details should see Levitin).^[2]

Criteria for a Definition of Data

The data life cycle suggests that data must be defined in a way that will account for the fundamental operations of defining models and views, collecting and updating values, storing, retrieving, and manipulating data, and presenting data and using them for a variety of purposes. The following criteria are also important in a good definition of data.^[3]

- *Clarity and simplicity*—This criterion holds for any good definition.
- *Nonreliance on the term information*—This criterion avoids circular definitions.
- *Agreement with common usage*—We want to understand the term data, not to create a new meaning for a common term.
- *Inclusion of conceptual and representational aspects of data*—Both are too important to leave out.
- *Wide applicability*—The definition should include data as diverse as meter readings and the contents of databases and document information systems.
- *Suggestive of quality dimensions*—The definition should lead to practical data quality improvements.

Data Defined

Many definitions of data have been suggested in the literature; the one that best meets the criteria discussed in the

previous section is based on the classic definition of the term accepted in the database community. (For an in-depth discussion see Whitmore).^[4] This definition is really a collection of definitions of several related terms.

A *conceptual model* or a *data model* is an abstract description of some part of the world, called the *universe* or *enterprise*, that associates, or maps, objects in the world to abstract objects in the model, called *entities*. The portion of the world modeled may include both physical and abstract objects. Characteristics of the modeled real-world objects and relationships between them are captured in the model as attributes. An *attribute* is a property of an object that can assume values from a set called the *domain* of the attribute. There are no restrictions on the elements of a domain; they may be numbers, strings, entities, sets of entities and so forth. An entity is said to have an attribute when the attribute applies to the entity. Entities in a conceptual model that share a set of attributes are grouped together as an entity type.

To illustrate these definitions, consider two conceptual models used to define the reader. Consider first the conceptual model employed by his/her employer. The entities in this conceptual model consist of all past or present employees. The attributes of interest include name, employee ID, status, department, and so forth. Each attribute has well-defined domains of permissible values, for example, the domain for the attribute department includes all departments (Human Resource, Finance, Operations, etc.) of the employer's organization (note that the domain may change as the organization changes). Besides indicating the properties of entities, attributes may be used as entity identifiers. For example, this conceptual model might use the Employee ID attribute as an entity identifier.

Within this framework, we define a *datum* or *data item*, as a triple $\langle e, a, v \rangle$, where e is an entity in a conceptual model, a is an attribute of entity e , and v is a value from the domain of attribute a . A datum asserts that entity e has value v for attribute a . *Data* are the members of any collection of data items. Returning to the example, a datum in the collection is $\langle \text{John Doe, Department, "Legal"} \rangle$, indicating that the department assigned to the employee John Doe is "Legal."

Note that the Internal Revenue Service (IRS) may also take an interest in the reader. The conceptual model it uses may overlap the employer's. For example, both include Name. But the employer's model may not include Year 2000 dividend income. Likewise the IRS's model need not include Department.

To complete this characterization of data, the mechanism of data representation must be included. A *data representation* is a set of rules for recording data triples on some medium. A *data recording* is a physical object interpretable (via a data representation) as a listing of data items. Representation of data values is accomplished via a *format*, or convention for recording data values using *symbols*, or representational elements. Publications data

might be recorded in a paper index, a card catalog, or a computer database. A typical mechanism places all data values for a particular entity together in a *record* consisting of a *field* for every attribute in which the value for the attribute is stored. In many cases, the representations for values in fields will follow traditional formats. For example, author attribute values are typically recorded in a "last-name-first" format using the Roman alphabet.

This definition of data satisfies the criteria discussed in the section above in the following ways:

- The definition is set in the context of conceptual modeling, so it accounts for the data life-cycle activities of defining models and views. It also matches the standard conceptual foundations in the database literature.^[5]
- The definition distinguishes data values, attributes, and entities, which are necessary to make sense of the data life-cycle operations of defining a model, of collecting and updating values, and of storing, retrieving, manipulating, and presenting data.
- The definition is simple; if necessary, it can be stated in precise mathematical terms so it is clear.
- The definition does not mention information, so information can be defined in terms of data without circularity.
- This definition of data accords with everyday uses of the word. For example, a water meter reading can be understood as a recording, using a certain data representation, of the value of an attribute (WaterConsumption) of an entity (the CUSTOMER).
- This definition accounts for both the conceptual and representational aspects of data.
- This approach is applicable in all studies of data in systems, including database systems, document information systems, and manual data systems.
- This definition of data lends itself to the study of all salient quality dimensions of data, as we will discuss below.

In summary, the ordered triple view of data meets all requirements for an adequate definition of data, and provides the necessary basis for a thorough consideration of data quality.

QUALITY AND QUALITY CONTROL

The most basic idea in quality is to "create and keep a customer."^[6] One collection of data that satisfies customer needs better than a second collection is of higher quality. It follows that the most important measure of quality is customer satisfaction and that a key component of any good approach to quality is determining who the customers are and understanding their needs. Although this is simple in principle, it is complicated enormously by a

Fig. 2 Data quality defined. Data are of high quality if they are fit for their intended uses (by customers) in operations, decision making, and planning (after Juran). (© Navesink Consulting Group.)

dynamic world: customer needs change continuously, new competitors enter the market, new offerings appear, and so forth. And data customers can have a stunning array of needs. A simplifying notion is that of “fitness for use,” as illustrated in Fig. 2, below.

Although data quality must ultimately be defined by the data’s customers, several characteristics stand out as important to most customers. These characteristics are called *data quality dimensions*. Given the definition of data above, quality dimensions can be classified according to three major quality concerns: quality of a conceptual model, quality of data values, and quality of data representation;^[7] alternative approaches developed by Massachusetts Institute of Technology’s (MIT) Total Data Quality Management Research Program can be found in.^[8–10] Finally, one can also take the point of view that customers should not be required to separate their requirements of data from those of database systems and that data quality dimensions should be viewed as a subset of all requirements. (See Redman^[7] for a comprehensive list of dimensions).

Quality of a Conceptual Model

A *conceptual model* provides a framework for a data set by specifying entity classes, their attributes, and attribute domains. In addition, various constraints, often called *business rules*, can be included in the model. Quality dimensions of a conceptual model can be grouped into six categories: content, scope, level of detail, composition, consistency, and reaction to change. (This grouping follows Levitin and Redman;^[11] see Flavin^[12] and Fidel^[13] for alternative views. See also Brackett^[14] for an in-depth discussion of a good data modeling practice).

Content

This category includes characteristics of the facts represented by the data. The most important of them is

relevance: the degree to which a model’s components are pertinent for the intended applications. Although the importance of data relevance seems obvious, lack of relevance has been singled out by several authors as among the most important issues in data quality.^[15,16] Another concern is that all model components have *unambiguous definitions*. The necessity and difficulty of achieving clear definitions is discussed by Brackett,^[14] Kent,^[17] and Thompson.^[18] The lack of clear definitions continues to plague many important databases (see Sy^[16] and Gardner^[19]). Finally, the *obtainability of values* for entities and attributes must be considered. Obtainability of values can meet various obstacles. For example, including gender information in a database may be illegal because it may lead to job discrimination. Obtaining blood types for all employees or citizens may not be affordable.

Scope

This characteristic involves the breadth of coverage of a model. A model should be both *comprehensive* and *essential*. In other words, a model must be broad enough to satisfy all the needs of its intended customers but not include unnecessary information. In practice, identifying the needs of even a single customer poses serious challenges for a data modeler. Integrating different sets of requirements to allow data sharing by several customers or applications as required for modern database management systems adds additional issues and difficulties.

There are several reasons for choosing a model broader than the one minimally necessary. First, the designer must usually create a model to accommodate both current and future applications. Second, redundancy can be introduced as a way to check data values. For example, a census form may ask for both the number of children in a household and a list of their names. Third redundancy speeds up some queries. For example, even though the number of employees in a DEPARTMENT can be calculated by checking the department attribute of all EMPLOYEES, it will be available more quickly as the value of the (redundant) attribute Number Of Employees. Unless justified for one of these reasons, the expense of obtaining, storing, and maintaining unnecessary data should be avoided.

Level of Detail

Choosing the proper level of detail for a conceptual model has two aspects. The first is exemplified by the choice of size of geographic regions for recording sales. Data might be recorded for a city, a county, a state, and so forth. This characteristic is called *attribute granularity*. Lower levels of granularity provide more detail and the opportunity of keeping more data (e.g., subtotals) for finding and correcting errors. On the other hand, a lower level of granularity leads to a larger volume of data. Detailed data may be harder to obtain and usually increase costs.

Customers may also be annoyed when presented with data more detailed than needed.^[20]

The other aspect of level of detail is called *domain precision*, the measurement or classification detail used in defining an attribute's domain. For example, measurements in inches are more precise than measurements in feet. Similarly, having 20 distinct values in a color attribute's domain is more precise than having 7. (See a realistic example in Sy and Robbin's^[16] discussion of the Standard Industrial Classification).

Composition

This characteristic concerns the structuring or grouping of facts represented by data. Each entity type of data model should be *natural*; that is, it should be a natural grouping of natural attributes with natural domains. This requirement can be met if each entity type has a sensible counterpart in the part of the world being modeled, and each attribute captures a single fact about entities and their relationships. Such an attribute typically represents some property (e.g., the gender of an employee) or it used for identification (e.g., the Social Security number of an employee). Unnatural "multifactor" attributes are often introduced to satisfy outdated implementation constraints. For example, an attribute may be defined to hold a code for both age bracket and gender in an effort to save storage space. Date^[21] discusses other examples and their consequences. Although multifactor attributes should be avoided, some well-established classification schemes incorporate secondary information. For example, room numbering schemes often code the floor into the number. It is hard to call this familiar scheme unnatural. (Things have a tendency to become natural when we get used to them.) Secondary facts may also be incorporated into values for redundancy and security.

In a well-composed conceptual model, each type must have a mechanism for distinguishing individual entities. This requirement, called *occurrence identifiability*, is often incorporated into the definition of an entity type. Usually, occurrence identification is accomplished with a *primary key*, one or more attributes whose value(s) uniquely identify individuals. For example, Social Security Number can serve as a primary key for an EMPLOYEE entity type.

A good model should also promote *homogeneous* types. This means that each attribute should apply to all individuals of the type. This does not preclude using values for "none," "exists but unknown," or even "existence is unknown" (each of these may apply, e.g., to Telephone Number).

Consistency

There are two aspects of this quality dimension. The first is *semantic consistency*, which requires consistency of definitions among related components of a model.

Problems often arise with definitions from different databases. For example, Whitmore^[22] cites a serious discrepancy in oil import figures reported by the U.S. Bureau of the Census and the Department of Energy caused by the differing definitions of "petroleum," "U.S.," and "month." Sy and Robbin^[16] discuss many examples of problems with U.S. government data. The second aspect of consistency is *structural consistency*, which requires consistency in combining a model's components. For examples, such commonly used attributes as Person Name, Address, Date, and Time Of Day should have the same structure across all entity types. Tasker^[23] has suggested standard structures for such attributes.

Reaction to Change

A conceptual model provides a framework for representing information about a part of the world, but both the world and customers' requirements change over time. A good model *must accommodate change*. We classify changes into four categories: addition or deletion of an entity (e.g., hiring or firing an employee), changing a value (e.g., changing a salary), changing a domain (e.g., introducing a new car model), and introducing a new attribute or entity type. The first two kinds of changes, called *updates*, are routinely performed in any computer-based database management or document information system without any change in the underlying model; the other two require changes in the model.

Most authors mention "flexibility" as the only design characteristic for accommodating change. In practice, changing a model is usually a serious and expensive task and the ability to accommodate change without redesign is an important practical need. We define a model's *robustness* as its ability to reflect changes in the world and its customer's requirement without design changes. The first step toward design robustness is to select attributes that will not change or whose changes can be easily accommodated. For example, Social Security Number is a more robust identifier of people in the United States than a Name (even if a name's uniqueness could be guaranteed) because it is easier for a person to change names than social security numbers. Another avenue to robustness is to anticipate changes and provide for them in the original design. For example, a company that currently produces sweaters with sizes "small," "medium," and "large" may produce other sizes in the future. No matter how robust a model may be, some design changes will have to be made eventually. A model's *flexibility* is its capacity to change to meet unanticipated demands. A good model is flexible as well as robust.

Quality Dimensions of Data Values

We group dimensions of data quality involving data *values* into four categories: accuracy, currency, completeness, and consistency.

Accuracy

The *accuracy* of a datum $\langle e, a, v \rangle$ is the degree of closeness of v to some value v' in the domain of attribute a considered correct for the entity e . Sometimes v' is referred to as the *standard*. If the value v is identical to the correct value v' , the datum is said to be *accurate* or *correct*. To illustrate, consider an EMPLOYEE entity identified by the Employee Number 314159, and the attribute Year Of Birth. If the value of Year Of Birth for employee 314159 is the year the employee was born, the datum is correct.

Accuracy is most easily measured in terms of inaccuracy. Inaccuracy for a single datum may be computed as the absolute difference between the correct value v' and datum's value v . For the example above, inaccuracy may be quantified as the absolute difference between the year of birth v' and the value v for the attribute Year Of Birth. The (in)accuracy of a database can be measured in two ways. *Field (in)accuracy* is the fraction of triples in the database with (in)correct data values. *Record (in)accuracy* is the fraction of entities in the database whose records are error-free; that is, the fraction of all entities in the database all of whose attributes have correct data values. Records are usually composed of several fields, so record accuracy is much lower than field accuracy. Furthermore, errors in different fields may be unimportant or disastrous. These last two observations suggest caution when judging database quality on the basis of error rate.^[24]

Accuracy and correctness are not as simple as they seem, especially when it comes to evaluation. It is often difficult to determine the standard. Sometimes there is not an obvious single correct value for an attribute, as is often the case in spelling, especially names. Sometimes the correct value is undefined, as when an entity identifier is wrong. In the example above, there may be no correct value for Year Of Birth if there is no employee 314159. It may also be difficult to quantify inaccuracy, even if the correct value is known, because the attribute in question may resist quantification, as do label, category, and description data. In summary, measuring data inaccuracy is often not easy when it is possible, and it is not always possible.

Currency

The ordered triple definition of data treats data as snapshots of part of the world. Most objects change with time, introducing opportunities for data to become incorrect or inaccurate. A datum is *current* or *up-to-date* at time t if it is correct at time t , and *out-of-date* at time t if it is incorrect at t but was correct at some time before t . Currency may be quantified by measuring how far out-of-date a value is. Database currency can be measured as the fraction of out-of-date triples in the database. As an example, suppose the annual salary of an EMPLOYEE can only

change at the start of a calendar year, and that some employee's salary was \$36,000 in 1992, \$39,000 in 1993, and \$43,000 in 1994. If during 1994 a datum shows the salary as \$43,000, it is up-to-date; if it shows \$36,000, it is two years out-of-date; if it shows \$42,000, it is simply incorrect.

Completeness and Duplication

The degree to which a data collection has values for all attributes of all entities that are supposed to have values is its *completeness*. A data collection may be incomplete because of missing values in the triples present or because some triples are missing entirely. In the case of missing values, the completeness of a single datum may be measured by whether or not it has a required value; a completeness measure for an entire data collection is then the fraction of triples in the collection with missing values. When a triple is missing a value, a special "null" value may be assigned for it. The meaning of null is different, depending on whether the attribute is mandatory, optional, or inapplicable. For mandatory attributes, the null value means value unknown. For optional attributes, the null value may mean that the attribute applies but we lack its value, or that the attribute does not apply, or that we do not know whether the attribute applies. For an inapplicable attribute, like Name Of Spouse for an unmarried person, the null value signifies that the attribute does not apply. In theory, these cases could be distinguished with different kinds of null values; in practice, having even one kind of null value causes problems for database systems.^[25,26]

A data collection may also be incomplete because some triples that should be included are missing. Missing record incompleteness can be measured by finding the fraction of records missing from the data collection.

Consistency and Integrity

Data are said to be *consistent* with respect to a set of conceptual model constraints if they satisfy all the constraints in the set.^[27] One measure of the consistency of a datum is a binary indication (Yes or No) of whether the datum satisfies all constraints. A measure for an entire data collection is then the fraction of inconsistent triples in the collection. Correct data must be consistent. The converse statement (consistent data are correct) need not be true. Said differently, consistency is necessary but not sufficient for correctness. Nevertheless, it is important to distinguish consistency as a special dimension because checking consistency is usually much easier and cheaper than checking corrections. Data integrity is sometimes used as a synonym for consistency, but sometimes it means data accuracy or correctness and, sometimes, security and concurrency control in database management systems.^[28–30]

Quality Dimensions of Data Representation

From a customer's perspective, the most important data representation issue is the means chosen to represent data values by symbols on a recording medium, called the *format*. The following are the four major formats.^[31]

- *String formats* represent values by character strings over some alphabet, including alphanumeric strings, and bitstrings. This category includes numeric coding schemes, most computer storage mechanisms, and most textual representations of data.
- *Positional/marking formats* specify values by marking a particular spot on a recording medium. This category includes coding sheets used in questionnaires and graphical methods.^[32–35]
- *Icon formats* use pictorial symbols to represent values.
- *Color formats* represent data values by colors.

The first two formats are the most widely used, but there are several applications in which the last two appear as well.^[36]

The most important quality dimension of a format is its *appropriateness*, both for meeting customer needs and using the recording medium effectively. Customers deal with representations of data, not data triples themselves, and their needs are of primary importance. They depend on two factors: the type of customer (human, mechanical, optical, etc.), and the task the customer is to perform (communication, analysis, storage, etc.). Reliable and convenient use of recording media is obviously of practical importance.

A format should result in a correct interpretation of values represented; that is, the format should be unambiguous. For example, a format representing three ratings with the digits 1, 2, and 3 is more ambiguous (to a human) than the one using the strings “worst,” “average,” and “best.” Ambiguity may also arise when a format does not specify a unit of measurement for quantitative data. Special care is needed with icon and color formats because there is not wide agreement about their meaning.

A third quality dimension of formats is *universality* or *portability*, which is the degree to which a format can be used by a wide range of customers. In this respect, specifying numbers with words of a natural language is inferior to using Arabic digits. Similarly, representing telephone numbers without area codes is inferior to including area codes. When using a color format, colors must be chosen bearing in mind that color-blind people can distinguish some colors but not others.

A good format must also be sufficiently *precise*, which means that there must be distinct representations for any two values in an attribute's domain. For example, formats for quantitative data must provide means for specifying numbers as precisely as required. A fifth

quality dimension is *flexibility*, which is the ability of a format to accommodate changes in the domain of values represented. This issue has arisen in many information systems struggling to adapt to real-world change.^[36,37] A sixth quality of a good format is its *ability to represent null values*. A good format should represent null values in a way clearly understood by customers; Celko^[36] retells the tale of the motorist who got thousands of traffic tickets because his license plate read “none.” Finally, a format should *make efficient use of the recording medium*.

DATA QUALITY MANAGEMENT

Over the last several decades, any number of quality techniques have been developed and applied. The greatest penetration has occurred in the manufacturing sector, where any number of industries now produce far better products at far lower cost. The service sector has begun to apply quality techniques, also with good success. And some organizations have begun to extend quality techniques to data.

Perhaps the most important lesson learned is that, more than anything else, an organization's leadership dictates the quality of its products, services, and data. While technical excellence is important, consistent, sustained management effort is essential.

Quality Systems

The totality of an organization's efforts that bear on quality define its quality system. Thus, the quality system includes leadership, management, and the application of tools to understand customer needs, measure quality, find and fix defects, and so forth. And while literally thousands of techniques have been tried, all support one of three basic quality management philosophies:

- So-called *first-generation* philosophy and techniques provide quality through inspection and rework of final products, hopefully, before they are passed on to customers.
- So-called *second-generation* philosophy and techniques provide quality by minimizing root causes of defects in the processes that produce final products. Here the term *process* means the sequence of work activities that produce and deliver products or services to customers.
- So-called *third-generation* philosophy and techniques aim to design processes so that defects cannot be produced.

Each of these approaches is discussed briefly in the following sections.

First Generation: Inspection and Rework

In this approach to quality, a product or service is inspected for conformance to needs before delivery to a customer. Products or services that fail inspection are either reworked or discarded. In the simplest case, everything is inspected, but more sophisticated acceptance sampling procedures can reduce inspection costs.^[38]

The strength of this approach is that it usually improves outgoing quality. Its major drawbacks are that inspections are often difficult and expensive, and reworking or discarding products or services is always expensive. Further, process quality levels tend not to improve beyond a limiting level. Inspection and rework is the first step that an organization takes to achieve quality.

Second Generation: Process Quality Management

The fundamental tenet of process quality management is that process performance can be made predictable within limits. A process operating within expected limits is in a state of *statistical control*. For such processes, statistical and other methods can identify process weaknesses and then changes can be made to improve process performance. For example, suppose a process for collecting and filling service orders is measured and found to be out of control. After study, several problems with ill-defined procedures are identified and eliminated. The process then operates in a state of statistical control with an average error rate of 0.1%. Further study of the process then reveals error-prone activities that can be improved, thereby reducing its average error rate to 0.05%. The net results of these activities are that: 1) they make the output of the process predictable and known and 2) they produce measurable improvements in process performance. (For a fuller account of this approach see Ishikawa,^[39] Wadsworth).^[40,41]

Process quality management requires some investment, but as processes are brought under control and improved, total costs go down (inspecting and reworking defects is simply much more expensive than preventing them). Furthermore, process quality management can produce sustainable quality improvements as necessary to satisfy customer needs.

Third Generation: Process Design

This approach attempts to make large improvements quickly by designing or redesigning a process from scratch rather than letting it evolve through process quality management. This goal can be reached by making the process simpler and less error-prone, often by incorporating higher technology in both the process and its design.^[42] A third-generation philosophy and supporting techniques are required to meet 6σ (six-sigma) quality

levels; today, symbolic of world-class quality (6σ equates to 3.4 defects per million).

Combining Quality Management Approaches

All three approaches to quality management discussed above have proven effective in countless instances, especially in manufacturing settings. The two process-based approaches are more advanced and more effective than inspection and rework for the following reasons:

- Defects are expensive to find and fix; detecting and removing a defect can cost up to 10 times as much as preventing it.
- Defects that customers find have a direct impact on customer satisfaction, the ultimate measure of quality.
- Experience has shown that world-class quality levels cannot be achieved solely through inspection and rework.

Despite their weaknesses, inspection and rework have their place alongside process quality management and process design, and mature quality systems combine all three approaches. For example, an organization may have carefully designed a process to minimize errors and may be managing it actively to steadily improve and optimize its performance. Nevertheless, a bad product or service may still find its way to a customer, where it must be replaced or fixed. A mechanism for inspection and rework may thus need to be present in even the most sophisticated environments.

Although quality approaches have been pioneered in manufacturing enterprises, they have also been effective in service industries.^[43] And experience confirms that they work for data as well. More specifically, experience confirms that the first two approaches work well. (See English,^[44] Loshin^[45] and Redman^[46] for examples). The next subsection reviews specific methods for applying these three general approaches to data quality.

QUALITY CONTROL APPROACHES APPLIED TO DATA

While all dimensions of data quality are important (at least to some customers), in this section, we focus only on data accuracy. It is important to all customers and is a good vehicle for illustrating the application of quality approaches to data.

First-Generation: Error Detection and Correction

The most prevalent method for controlling and improving data accuracy is to detect and correct inaccurate values. The simplest procedure is to compare data values to the world and fix those that are wrong. For example, consider

an employee database containing data on work and home addresses. It is common for the administrators of such databases to survey employees regularly to verify and correct their addresses. Depending on how cooperative employees are (and whether or not the address verification and correction form reaches them), this procedure can work very well. It is costly, however, and yields no sustained improvement in data quality over time; after a survey, the accuracy of data will deteriorate steadily until the next survey is done.

A second technique, called *database bashing*, is also used frequently when data values are stored in two or more databases. Corresponding values in the databases are compared, and when a disagreement is detected, an investigation finds the correct value, and the databases are fixed. This technique has several advantages over comparing all values to the real world. It is easier to manage and tends to cost less, especially when the databases can be compared using a computer, but, like all techniques based on inspection and rework, it does not yield sustained quality improvement.

A third technique, called *data editing*, involves computerized checking of data values against constraints. These constraints may be simple or sophisticated and typically involve the following:

- *Checks of a single field.* For example, a field whose domain is {0, 1, 2, ..., 10} may have its values checked against this set.
- *Checks of several fields.* The checked fields could be in a single record or in several records. For example, a field recording the Number Of Employees of a DEPARTMENT might be checked by examining the department field of all EMPLOYEE records and counting the EMPLOYEES in the DEPARTMENT.
- *Probabilistic field checks.* For example, a record with a gender field value of female and a height field value of 78 in. is unlikely.

Such constraints are often called business rules. See Ross^[47] for further details. Once a record is found to be in error, further investigation locates and corrects the offending field(s). This technique may be used in the data life cycle during the activities of storing data values, retrieving data values, and manipulating data values, or as part of special data cleanup activities.

Data editing is popular because it is (apparently) computationally cheap. It is often difficult to generate an effective and complete list of edits, however.^[14,48] Once errors are found, it is still expensive to investigate and correct them. Finally, data editing provides no lasting quality improvements.

In summary, inspection and rework methods are not very effective for improving data quality because they are conducted downstream of data-value creation, usually either during a storage activity or during usage activities

of the data life cycle. Although these methods result in short-term data quality improvements to specific data values, they cannot provide lasting improvements because they do not attack the sources of errors.

Second-Generation: Prevent Errors at Their Sources

An alternative to error detection and correction is to focus on processes that create data values. Conceptually, this is simple. As in manufacturing, one must first achieve a state of statistical control. Errors are then reduced by identifying where and how they occur and changing the process to prevent them. Improvements made this way require more effort than inspection and rework but are sustainable and, therefore, cheaper in the long run.

But there are many practical problems. One problem stems from the fact that data move around the organization so quickly. Data created to satisfy a customer's order one day are used to manage inventory, to track sales, to plan next year's marketing campaign, and so forth, the next day. Data customers are harried in doing their current jobs, be it managing inventory, tracking sales, or planning next year's marketing campaign. When confronted with inaccurate data, they are simply more inclined to correct them or compensate for poor quality in some other way, than they are to seek out the sources of incorrect data.

That said, many organizations have made substantial improvements. And they have lowered costs and sped up their business processes and decision-making (error detection and correction takes time and costs money) as a result. Ten "best practices" have been observed.^[7] These are summarized as follows.

1. Senior management recognizes the importance of high-quality data and has mobilized the organization to improve. And they have focused data quality efforts on the most important data.
2. The organization holds those who create data responsible for the quality of data they create. This includes both internal and external data sources.
3. The organization identifies and actively manages its most important data suppliers.
4. The organization identifies and actively manages its most important internal business processes.
5. The organization recognizes "social issues" around data (such as that noted above) and actively manages data. It attaches value (often monetary) to data.
6. The organization understands "the most important needs of the most important customers." Data quality efforts are thus focused on the most important data.
7. The organization measures data quality levels. Measurement can be difficult. After all, data do not have physical properties such as size, weight, and impedance. Fortunately, good measurement information

can often be obtained cheaply. One simple method piggybacks process measurement on data-editing activities: failed edits can be classified and counted, and these measurements used for quality control and improvement. AT&T has developed a useful technique called *data tracking*^[49] for better process measurement and error detection and localization. Data tracking follows data through a process to determine where data are corrupted. Subsequent investigation identifies the root cause(s) of errors and removes them.

8. Statistical control of data sources is achieved. Control implies that data quality levels will be predictable into the future. And controlled processes are more easily improved.
9. Organizations with the best data are good at defining and conducting improvement projects that get to the root causes of error and eliminate (or at least mitigate) them.
10. Organizations with the best data set and meet aggressive targets for improvement. Indeed, they focus less on actual quality levels than on the rate of improvement.

Third Generation: Process Design for Data Quality

The third data quality improvement approach is to design or redesign processes to minimize errors. This approach is usually initially more expensive than either inspection and rework or process quality management, but, when successful, it yields large gains in a short time and may be cheaper than either one in the long run. Typically, process design introduces new information technologies. For example, an automatic bar-code reader may be introduced into a process because it reads product codes faster and more accurately than a person can.

Limited experience in designing processes confirms that the following ideas^[7] can work well:

1. Replace humans with automation in repetitive tasks in which people are likely to make errors, such as data input, data transcription or reformatting, and data searching. More generally, automating well-defined tasks and processes yields gains in speed, productivity, and quality. Conversely, automating poorly defined tasks and processes rarely works.
2. Design processes to optimize end-to-end performance, not the performance of subprocesses.
3. Capture data as close as possible to its original source. Minimize duplication, data transcription, data transformation, and redundant data storage.
4. Employ a “just-in-time” philosophy to data creation.
5. Design data editing and handling of exceptions into the process.

6. Employ simple data codes and extensive, easy-to-access data dictionaries.
7. Data quality measurement should be designed into processes that create data from the beginning. This provides nonintrusive mechanisms that can be used for quality improvement and control, especially when measurement can be built into the software that supports a process.

Process design for data quality is a promising area for further work in the future.

DATA QUALITY AND THE INTERNET

Even a casual glance confirms that the importance of data, and, hence, data quality, has grown enormously over the past decades. Many factors are involved, including the transition to the information economy, the tremendous gains in all sorts of information technologies, and the thirst for ever-more detail to support decision makers. As the importance of data has grown, so too has the need for data quality. And there is no end in sight.

The Internet, thus, is the latest in this series of technological advances and social changes. As this is written (summer 2001) the Internet is just beginning to change the data quality landscape. While the impact will evolve as the Internet evolves, a few points about data quality and the Internet are pertinent.

The first observation is that the Internet creates new data customers. Organizations are publishing data on the Internet that they had previously held as proprietary. Those who view these data almost certainly have different needs than internal customers. They have not been trained on how to interpret data, making clear definition and ease of interpretation more important. They are not familiar with the nuances inherent in the data and could be more easily misled, making accuracy more important. Their native language may be different, making dimensions associated with data presentation more important. Perhaps most importantly, they have different needs and they themselves are different. Some, such as those seeking medical advice relevant to a particular condition, may be focused and discerning but not technically sophisticated. Some, such as college students desiring to complete a report, may be technically advanced but in a hurry and not too careful about what they accept as fact, and so forth.

The second change involves the use of the Internet to conduct business operations. Supply chain management is a good but, by no means, only example. Supply chain management involves using the Internet to order goods and services, arrange and make payment, coordinate deliveries, and so forth. Without the Internet, organizations spend an enormous amount of time and money on supply chain management. Supply chain management works

reasonably well, and the Internet offers the opportunity to do so at far lower cost. But only if the data are of high quality.

Third, the Internet makes things possible that are currently not. We do not wish to enter the debate about whether or not “the Internet changes everything.” See Porter^[50] for a compelling, though not proven, viewpoint that it does not. But it does appear that opportunities to replace standard or commodity products and services with products and services tailored specifically to the individual may indeed become realities. Certainly health care providers are beginning to talk about drugs formulated specifically for individual patients. “Markets of size one” form part of the hope of customer resource management, and so forth. All share the following characteristics:

- They require vast quantities of individual-specific data.
- The impact of poor data is much greater.

CONCLUSION

To summarize, data quality is a subject of primary importance in the twenty-first century. Many factors, including the Internet appear to be making high-quality data more important than ever. Improvement must be based on preventing errors at their sources.

Deaf and Hearing Impaired: Communication in Service Contexts [*ELIS Classic*]

Warren R. Goldmann

National Technical Institute for the Deaf, Rochester Institute of Technology, Rochester, New York, U.S.A.

Abstract

From the author's text: "This article provides insights on deafness, deaf and hearing-impaired people, the varied means of communication they use, and basic communications skills useful in communicating with deaf patrons. Suggestions for further reading and study are given, as are sources of in-depth information about deafness and related subjects. Minor modifications to the manner in which one converses can facilitate communication with people with various degrees of hearing impairment, enhance the level of mutual comfort of library personnel and deaf patrons alike, and lead to more productive interaction. Such accommodations can and do represent a significant step toward making libraries accessible to hearing-impaired and deaf people."

—*ELIS Classic*, from 1995

INTRODUCTION

Ideally, libraries should be accessible to all potential users without regard to any disabling condition. As depositories of information, libraries constitute a key institution of democratic societies, yet people with hearing impairments often discover that communication difficulties can be a serious barrier to their using the library to its full potential.

Librarians typically communicate with people of diverse backgrounds and characteristics. Inevitably, some of these people will be deaf or hearing impaired. According to a 1974 study at the Deafness Research and Training Center at New York University, approximately 7 percent of the population is hearing impaired, and slightly under 1% is profoundly deaf.^[1] Another writer estimates that approximately 14% of the population is affected to some degree by hearing loss, including that caused by aging.^[2] Hearing impairment is the single most prevalent chronic disability in the United States.^[1]

The Americans with Disabilities Act of 1990 mandates that public accommodations, including libraries, must strive to provide auxiliary aids and services to clients and consumers without charge. Such aids and services appropriate for deaf and hearing-impaired clients include qualified interpreters, notetakers, written materials, telephone communication devices for the deaf (TDDs), assistive listening devices, and closed or open captioning.^[3]

Unusually large numbers of deaf and hearing-impaired people live and attend colleges and universities in Rochester, New York, and Washington, D.C. A number of libraries in these areas, particularly the collegiate libraries of Rochester Institute of Technology (RIT), (which is the

host institution to the National Technical Institute for the Deaf) (NTID) and Gallaudet University (in Washington), have addressed the communication needs of hearing-impaired people in various ways.

For example, at RIT there is a reference librarian specializing in services to deaf and hearing-impaired students and offering specialized training to other librarians in meeting the needs of these patrons. The coordinator of the staff resource center of the NTID serves all NTID faculty and staff, including those who happen to be deaf or hearing impaired. Both have developed sign language proficiency. The former offers instruction in the use of the RIT library for deaf students, provides library orientation tours in sign language, writes and distributes informational and public relations flyers about library services available to deaf patrons, and teaches weekly sign language classes for other RIT reference librarians. Three TDDs are available in this library, including one available for student use, thus making the library accessible by telephone for deaf patrons. An extensive collection of books and information about deafness is maintained.^[4] In the greater Rochester community, several public libraries have also made themselves accessible to deaf patrons through the provision of TDDs.

Aside from the offerings of these few libraries, however, relatively little is available in the way of skilled personnel or adapted facilities to meet the needs of deaf and hearing-impaired patrons. Librarians in general still tend to be unprepared to cope with the special and varied communication needs of these patrons or to promote action toward making their facilities accessible to them. In spite of the prevalence of hearing loss in this country

that disability still remains a serious barrier to communication in the use of libraries. [Generally speaking, that] barrier is a 2-way obstacle—people in the hearing world do not communicate with those in the non-hearing world, and vice versa.^[2]

This article provides insights on deafness, deaf and hearing-impaired people, the varied means of communication they use, and basic communications skills useful in communicating with deaf patrons. Suggestions for further reading and study are given, as are sources of in-depth information about deafness and related subjects.

Minor modifications to the manner in which one converses can facilitate communication with people with various degrees of hearing impairment, enhance the level of mutual comfort of library personnel and deaf patrons alike, and lead to more productive interaction. Such accommodations can and do represent a significant step toward making libraries accessible to hearing-impaired and deaf people.

BACKGROUND

Terminology

Hearing impairment is the most general term used to describe all types and degrees of hearing defects, ranging from slight loss to profound deafness.

“Deaf” individuals can discern no meaning in perceivable sounds. Additionally, the capitalized word *Deaf* is used by some authors to refer to profoundly deaf people whose community and culture are based on both common experiences (such as attending institutions or programs for deaf students) and a common language, American Sign Language (ASL).

“Hard-of-hearing” describes individuals whose sense of hearing, while deficient, is still somewhat functional. They can comprehend speech to some extent with or without a hearing aid, and generally depend on speechreading, facial expression, and gestures (sometimes including sign language) to supplement what they do hear.

Additional communication and cultural characteristics of both groups are discussed later in this entry.

Deafness and Deaf People

Over the course of their lifetimes, millions of Americans live with some degree of hearing loss. *Congenitally deaf* people (those who are born with profound deafness) are in the minority, but still comprise many thousands of individuals. Significantly larger numbers are *adventitiously deaf*, having lost part or all of their hearing later in life, at any time from infancy onward. *Prelingual deafness* describes the loss of hearing before the acquisition of language, usually before 3 years of age. *Postlingual deafness* describes hearing loss occurring after (often long after) language acquisition.

A number of different factors determine the impact of deafness or hearing loss on the individual. These include the type and severity of the loss, the age of onset of hearing loss, and whether the loss is sudden or gradual. Schooling, life experiences, personality, and communication preferences are other determinants of an individual's adjustment to deafness and the communication style and skills developed.

Causes of hearing loss are diverse. Common etiologies include genetics, illness, trauma, exposure to excessively loud sounds over a period of time, and gradual deterioration due to aging.

Severity of hearing loss may range from a slight and correctable loss to profound deafness, in which case the individual literally cannot hear any sound. Moreover, there are different types of hearing loss, such as middle ear problems, or nerve deterioration or damage. Hearing impairment will usually entail greater difficulty in detecting certain frequencies than others within the spectrum of audible sound. For example, if someone has difficulty hearing high frequencies (as opposed to low or midrange frequencies), the sound of the final “s” that forms the plural of many words is often entirely missed.

Modern hearing aids can be adjusted to some extent to compensate for uneven hearing loss over the range of audible frequencies, particularly when the severity of loss is minimal. In such cases, hearing with an aid may be close to normal. However, when the hearing loss is severe, even a powerful aid may not be able to compensate evenly for losses that are distributed across the entire audible frequency spectrum. The result is that sounds are distorted and therefore harder to recognize and distinguish. The greater the severity of loss, the less effective a hearing aid is in helping an individual receive and understand information through sound alone, and the more the individual must rely on alternative strategies. Speechreading, manual communication, gestures, writing, or combinations of these methods are examples of such strategies used in communication between deaf and hearing people.

The age at which an individual experiences hearing loss or becomes deaf has a great impact on language acquisition and intellectual development. Language is ordinarily acquired through the frequent and repeated exposure to speech, usually beginning in infancy. An individual who learns speech and language patterns through such early exposure will normally retain and continue to use them even if his or her hearing deteriorates later in life. On the other hand, developing speaking skills is infinitely harder and slower for someone born deaf. Without intervention, the deaf child

must grow up not only unable to speak but denied even a concept of language, that indispensable instrument of thinking and reasoning. . .not only unable to communicate with others, he cannot even communicate with himself.^[5]

It is extremely difficult to learn to produce sounds that one has never heard and that may also be difficult or impossible to read from a speaker's lips. An individual who is born with moderate hearing loss or who experiences such loss early in life will hear imperfectly, which often results in corresponding difficulties with English because of the lack of a language-based frame of reference.

In contrast to blindness, deafness is most commonly an invisible handicap. However, there are common signs and symptoms indicating that a person may have a hearing loss.

Look for these signals when the person

- Asks to have things repeated often
- Does not react to loud noise
- Does not always respond when spoken to, or responds inappropriately
- Misunderstands conversation
- Has trouble hearing in group settings
- Complains that people are mumbling
- Has difficulty hearing women's or children's voice, but can hear deeper tones, such as men's voices
- Must be close to the person speaking
- Speaks too loudly or softly in conversation
- Strains to hear
- Ignores sounds coming from behind
- Has nasal speech or less distinct articulation
- Turns head towards the person when speaking^[6]

Communication Modes

Adding to the diversity previously described are disparate communication modes, strategies, and preferences. In the United States and elsewhere, communication methodology has been hotly debated among both deaf and hearing people for over a century. Even today, educators, doctors, and other professionals; parents; and deaf people themselves still argue over whether deaf children should be encouraged and taught to communicate orally (i.e., through speech and speechreading only), in ASL, in signed English, or through a combination of methods.

In describing the disparate communication strategies used by Deaf and hard-of-hearing people, respectively, certain generalizations may be made.

Deaf people, particularly those who are prelingually deaf and/or are born to deaf parents, rely primarily on vision, although some may use residual hearing to supplement their communication. Members of this group:

- Communicate through sign language and/or speechreading
- Use sign language interpreters
- Use Telecommunication Devices for the Deaf (TDDs) and Telephone Relay Services
- Use visual signaling devices for doorbell, telephone, sounds of baby crying, etc.

- Sometimes use specially trained "hearing dogs"
- Use closed-caption decoders for television viewing
- Generally are members of the Deaf culture.

Hearing impaired people rely primarily on hearing supplemented by amplification, and use their vision to supplement their communication. Members of this group:

- Generally do not use sign language
- Generally do not use interpreters
- Generally do not use TDDs or Telephone Relay Services
- Communicate using amplification and through speechreading
- Use hearing aids
- Use Assistive Listening Devices, such as induction loops, FM and infrared systems, and telephone speech and hearing amplifiers
- Use visual signaling devices
- Generally are not members of the Deaf culture.

There are some areas of overlap in the communication strategies used by these two groups.^[3] Obviously, there is no typical deaf person; there is tremendous diversity among people with any degree of hearing loss.

Misconceptions about Deafness and Deaf People

Misconceptions about deaf people are common among hearing people who have little or no direct contact with deaf individuals. The same is true about the various means used by deaf people to communicate among themselves and with their hearing counterparts.

For example, good speech is not necessarily an indication that a hearing-impaired speaker can also hear well. People who lose their hearing later in life may speak almost perfectly, in spite of profound deafness. Late-deafened adults lose the ability to monitor their own speech, which usually results in deterioration of speech quality. Sometimes this deterioration leads others to suspect a speech impairment rather than the deafness that actually causes it.

A common first question asked of deaf people is, "Can you lipread?" Although most deaf people do get information through observing lip movements, skill, experience, and comfort in speechreading vary tremendously. Very few deaf people develop sufficient speechreading skill for it to become their primary means of understanding others; often they will depend more or less exclusively on other means of communication because of great difficulty with speechreading. Some deaf individuals do learn to speechread so well that hearing people may be unaware of, or forget, their deafness.

Wearing a hearing aid does not necessarily imply that the wearer can "hear" in the sense of understanding speech

as a hearing counterpart would. In cases of severe impairment, wearing a hearing aid may be of little value beyond alerting the wearer to environmental sounds that are in themselves unintelligible.

COMMUNICATION WITH DEAF PEOPLE

Speaking and Facial Expression

Although speaking louder to a deaf or hard-of-hearing person is a natural inclination, this rarely, if ever, enhances comprehension. A profoundly deaf person will still hear nothing, no matter how loudly a message is spoken. Additionally, a hearing aid wearer may experience both distortion and pain when shouting or abnormally loud speech is amplified.

Leaning forward or speaking into a deaf person's ear are also counterproductive, if natural, responses to the person's deafness. When this occurs, speechreading becomes harder or impossible for the deaf person, because of the difficulty experienced in focusing on the speaker's mouth. As Wright points out, the speechreader must at all costs keep his or her line of vision to the other's face.^[5]

The use of facial expression appropriate to the tone and content of the message is of considerable help in communicating with deaf people. Speakers whose facial expression, gestures, and animation supplement spoken messages appropriately will generally be much more readily understood than those who do not provide these additional message clues.

Facial expressions are also crucial in conveying the intensity of a message. Particularly for deaf people who rely heavily on sign language, they modify both signed and spoken messages in a manner analogous to the way adjectives and adverbs modify spoken English for hearing people. Whether the speaker is mildly amused, delighted, perplexed, or angry, his or her thoughts might be expressed in essentially the same signs (with some variations in pace and intensity), but facial expressions are what convey the mood being expressed.

Overcoming any personal or cultural biases that inhibit the expression of feeling through facial expression and body language will convey the intended weight and meaning of a message to deaf patrons much more effectively.

Speechreading

Lipreading entails deciphering verbal messages through watching lip movements. Speechreading, on the other hand, not only encompasses lipreading, its most important component, but also incorporates many other visual clues that assist in understanding the spoken message. Such clues include facial expression, gestures, pantomime, rate of delivery, and eye contact. Even hearing people develop

and use some speechreading ability, often unconsciously, especially when background noise interferes with hearing.

People with hearing impairments vary greatly in their ability to speechread, even when other factors, including educational level attained, are essentially equal. Words and concepts must obviously be part of an individual's vocabulary and experience to be recognized through speechreading. Thus, a deaf individual who has never heard the patterns of spoken English will most likely find it difficult or impossible to speechread.

David Wright, a deaf Oxford University graduate, explains how complex lipreading is, even under ideal conditions

Lipreading is not simply a physical operation in which the eye has learned to interpret for the ear; it is also an intellectual exercise. Lipreading is ninety percent guesswork, because while most vowels are easily distinguished, many consonants are not, since those are often produced by nearly identical lip movements. This means that in effect a great number of words and syllables which are distinct in sound appear to the eye as like as peas. The alternatives can be so many that it may take a lipreader a few seconds to make the choice while he runs the various possibilities through his mind.^[5]

A missed key word can make an entire sentence incomprehensible to a speechreader. Words used out of context, as when a speaker changes the topic of his communication suddenly, are usually difficult to recognize. Stuttering and accents interfere with speechreading, as do poor lighting and visual interferences and distractions, including but not limited to bushy moustaches, objects in the mouth, or people or objects moving in the background.

Fortunately, the typical library, characterized by good lighting (i.e., bright, indirect, and uniform) and relatively few visual, tactile, or auditory distractions, is conducive to speechreading.

Although some deaf people speechread remarkably well in spite of the difficulties mentioned, it is important not to assume that every hearing-impaired person can speechread well enough so as not to require other supplemental means of communication.

Sign Language

The use of gestures is a natural communication channel for many people, particularly within and across certain cultures, and is as old as humankind. Deaf people have long communicated with one another through gestures and signs of their own invention. In various countries, some of these sign systems have become formalized into languages.

The | French | Abbé Charles Michel de l'Epeé convinced himself that gestures and signs were the natural language or "mother tongue" of the deaf-born, and therefore set out

to construct and codify a sign language based on the natural signs' that he had learned from his own pupils.^[5]

American Sign Language stems from this French sign language, as well as from a native American sign language. As is true in the cases of other modern languages, ASL continues to evolve.

Particularly over the past thirty years, linguistic studies have shown that ASL has a complex, systematic syntax of its own that differs dramatically from that of English. Moreover, the order in which concepts are signed and the ways in which they are modified are considerably different.

Just as the tone of voice in articulate speech modifies the sense of a word, the meaning of a particular sign can be modified by an expressive variation of gesture while making it.^[5]

In recent years, ASL has been recognized as a language in its own right. Many deaf people, as well as organizations such as the National Association of the Deaf, have become increasingly assertive in advocating ASL as both their language of choice and of instruction.

American Sign Language is a purely visual/gestural language, and thus has no written form. However, in the 1950s and 1960, William Stokoe, a Cornell University researcher, originated a system of symbols that accurately describe the finger, hand, face, and body movements that constitute ASL. His efforts, combined with the general recognition of ASL as a distinct language, have resulted in the publication of various dictionaries and instructional material on ASL. This in turn has led to greater standardization of ASL throughout the United States.

Many Deaf people and their advocates, notably organizations such as the National Association of the Deaf, have become increasingly assertive in advocating ASL as their language of choice in both social and instructional settings.

Fingerspelling

Simple, distinct handshapes are used in fingerspelling to represent the letters of the alphabet, as well as the digits 0 through 9. Letters are formed one after another to spell out words; slight pauses separate words from each other. Many of the letters of the alphabet are obvious in their manual representations.

Fingerspelling is most frequently used to supplement sign language, as when no sign for a particular concept exists, or when greater clarity or emphasis is desired in conveying a word or name. Because the number of letters and digits is tiny compared to the number of distinct signs, fingerspelling can be learned much more rapidly than sign language.

Simultaneous Communication and Total Communication

The use of *manual communication* (including both ASL components and fingerspelling) along with *oral communication* (speech and speechreading) is called *simultaneous communication*. This approach to communication (both to and among deaf people) tends to follow more closely the syntax and word order of English.

Total communication involves using everything at one's disposal to communicate, including simultaneous communication as just described, plus gestures and mime. Deaf people who normally use only ASL when communicating among themselves sometimes attempt to use speech as well as a word order more closely resembling that of English when communicating with hearing people.

Learning Sign Language

For those interested in developing or enhancing sign language skills, sign classes are offered by many schools, colleges, and universities, as well as by organizations serving the deaf community. The Monroe County Association for Hearing Impaired People in Rochester, New York, is one such organization. Many bookstores offer books on sign language (including fingerspelling), pictorial dictionaries, manuals that explain sign usage and word order, and collections of specialized signs.

As is true in learning any other new language, extensive practice is necessary to develop proficiency in manual communication. Interaction with a knowledgeable instructor and with deaf people is far preferable to self-instruction, because motion, mime, facial expression, intensity, and other visual clues, such important components of sign language communication, are best learned from this interaction.

However, even the use of fingerspelling alone can make a tremendous, positive difference in communicating basic information to a deaf person. So can learning and using a few signs relevant to the messages most often conveyed. This is all the more true if one is careful to verify the correctness of the signs used before using them routinely. Any appropriate communication adaptations, such as fingerspelling, the use of basic signs, or writing, help convey to a deaf person one's willingness and desire to communicate.

If asked, many deaf people will gladly provide helpful feedback to someone who is learning sign language. In communities with large concentrations of deaf people, it may be possible to find a professional (for example, a certified interpreter or teacher of sign language) who could evaluate one's skills more formally and provide feedback on appropriate or inappropriate communication strategies.

Writing to Communicate

Writing is one of the best ways to get a message across to a deaf person, especially when speech does not seem to be conveying the desired message. Writing information is particularly helpful when the message is detailed or when accuracy is essential. Brevity and simplicity often facilitate this means of communication, particularly in communicating with an individual whose proficiency in English is not well developed. Writing only the essential words of one's message may prove to be entirely sufficient.

Because ASL word order is so different from that of English, individuals whose primary language is ASL encounter some of the same difficulties with English as do others for whom English is a second language. Since qualifiers other than tenses, adjectives, and adverbs (e.g., facial expression, and rate of delivery) are used to modify ASL messages, the writing of deaf individuals sometimes exhibits errors somewhat comparable to writing errors of other nonnative users of English.

Questioning and paraphrasing by both the hearing and deaf persons can help clarify the intent and meaning of a written message when necessary.

OPTIMIZING CONDITIONS FOR GOOD COMMUNICATION

Managing the Communication Environment

Good lighting, appropriate position, unobstructed vision, and minimal distractions are essential to optimal speechreading. Although a resourceful and assertive hearing-impaired individual will try to position himself so as to optimize his own understanding, a speaker can also do much to optimize that communication. Many of the suggestions that follow are effective regardless of the hearing-impaired person's preferred communication mode.

Whenever possible, the speaker should

- Position herself so that the main source of light shines directly on her own face. Backlighting, which silhouettes the speaker's face, makes speechreading difficult or impossible.
- Position himself so that his face is at the same or a slightly higher level than that of the hearing-impaired person, rather than the other way around. This facilitates speechreading.
- Maintain eye contact. As difficult as this may be in some cultures, eye contact is of great importance in communicating with hearing impaired people. As Wright puts it:

The divining of people's moods and intentions from their eyes is so much easier (since it makes less intellectual demand) than the reading of their actual words.^[5]

Avoid noisy backgrounds or locations where there is a lot of motion that can be distracting. Move to a quieter spot if necessary.^[6]

General Suggestions for Interactive Communication

An individual's deafness, communication skills, and preferences remain invisible until he begins to communicate. The manner in which a deaf person initiates communication with a hearing person provides clues as to how he or she prefers to communicate in that situation. This might, for example, be through speech, a written note, gestures, or a signed message. Communication occurs through many channels other than just speech or sign language. Gestures, mime, facial expression, writing, and even drawing can be used to communicate. The less a person hears, the more important visual aids become in facilitating understanding.

It is best to respond using whatever communication techniques seem most appropriate at the moment and are within the speaker's current repertoire. Through experience and practice, and with background information of the kind presented here, hearing people may develop the ability to recognize and adapt skillfully to the diverse communication needs and preferences of hearing-impaired people.

The following tips will help in communicating with these patrons.

Initiating Communication

- Always get the hearing-impaired person's attention before starting any communication. This may be accomplished by moving into the other's line of sight, by touching him or her gently on the arm or shoulder, or by using other means that seem appropriate under the circumstances. Try not to startle the person.
- Establish and maintain eye contact.
- "Face the person directly. Stand still to communicate from a reasonably close, yet comfortable, distance."^[6]
- "Ask how you can facilitate communication. People appreciate being asked. You may be doing everything just fine, or your listener may need for you to talk slower, slightly louder, or make some other adjustment. By asking how to help, you show your desire to communicate clearly."^[6]

Adapting Your Communication to the Needs of the Hearing-Impaired Person

- Speak in a normal tone of voice. Don't speak loudly; doing so may embarrass the other person by drawing attention to his or her disability, and it usually does not enhance comprehension.

- Enunciate words distinctly, but without exaggeration. Exaggeration changes the appearance of speech on the lips to the point where words may actually become harder to recognize. Try not to mumble.
“Articulate: move your lips as well as the best new seaster on television.”^[6]
- Speak at a moderate, uniform rate, and with normal rhythm. Slow down delivery only enough to be able to enunciate clearly. Extremely slow or excessively rapid speech may be harder to speechread.
- Paraphrase messages when appropriate. If one or two repetitions of a word, phrase, or sentence do not seem to be conveying the message, try synonyms. Emphasize the key words in the message, as through repetition or by fingerspelling or writing these words.
- Use any gestures (or mime) that seem appropriate in helping to convey the desired message or meaning. If necessary, demonstrate an action or outline the shape of an object being discussed. For example, opening one’s hands as one would open a book both conveys a clear meaning and is actually the sign for “book.”
“Give other clues to clarify miscommunication.”^[6]
- Minimize behaviors that make speechreading more difficult, such as gum chewing, eating, or covering the mouth in any way while speaking. Also minimize head or body movements, unless they reinforce a spoken message.
- “Ask for feedback to know [whether or not] the person is understanding the conversation. Do [whatever else] you can to further enhance communication.”^[6]
- In a session where many new terms are being used, provide the new vocabulary in written form prior to the session.
- Make use of visual aids as much as possible. Be sure they can be seen clearly from all points in the room.
- Repeat questions or statements from the audience before answering or commenting.
- Depending on the format of the program, provide special seating for persons with hearing loss, so that they can see the speaker’s face and read captions.^[2]

Because of the diverse nature of hearing loss and that of the social, language, and educational experiences of people with hearing impairments, there are marked differences in communication preferences from one deaf person to another. Even though any proficiency in sign language on the part of a hearing person demonstrates caring and commitment to communicating, not every deaf person necessarily knows sign language or appreciates its use. Some deaf people still prefer to rely on speech and speechreading, especially if they themselves are not proficient in the use of sign communication.

Particularly after one has developed a repertoire of communication skills, asking deaf patrons which communication mode or modes they prefer is appropriate and will be appreciated.

CONCLUSION

As this article demonstrates, there are many straightforward, common sense things one can do to facilitate communication with hearing-impaired people. The desire to communicate and the willingness to adapt one’s communication to the needs of the individual deaf person, combined with patience and empathy, are more important than extensive sign language training. Positive experiences in communicating with deaf individuals will more often than not quickly enhance one’s comfort level in such situations, as well as that of one’s listeners.

All the topics in this article are discussed extensively in published works, including books and journals. The bibliography lists recent works, as well as several classics, under several headings: Services for Deaf and Hearing Impaired Library Patrons, Deafness, Communication, and Sign Language. Organizational sources of further information and of relevant services are listed.

Demonstrating Empathy with the Listener

- “Be patient if your listener seems slow to respond. The person may just need a little time to piece together what was heard or seen. This is the processing time needed to use two senses (sight and hearing) to receive communication. Impatience may show on your face and could create tension for your listener, which only makes further communication more difficult.”^[6]
- “Stay positive and relaxed. If you appear frustrated or anxious, the person with a hearing loss will find it more difficult to continue the conversation or (to) give you the feedback you need to make sure you are communicating effectively.”^[6]
- If using an interpreter, talk *to* the hearing impaired person, not about him or her. Remember that the communication is with the hearing impaired person, not with the interpreter. Again, maintain eye contact with the former.

Facilitating Group Communication

- Aid deaf and hearing impaired persons, when applicable, with an outline, summary, script or printout, prior to a meeting.

NOTE

This article is an adaptation of.^[7]

Department of Industrial Management and Logistics, Lund University, Lund, Sweden

Abstract

This entry provides a description of the vast area of decision sciences from an operations research/management science (OR/MS) perspective. This means that the focus is on how quantitative models can be used for improving the quality of decisions. After describing and explaining a general conceptual approach to quantitative decision modeling, some important, commonly used decision models and methods are considered in more detail. The list includes both deterministic models such as linear programming (LP), integer programming (IP), and economic lot sizing, as well as stochastic models for safety stock decisions in inventory management. Various generalizations are also discussed together with brief comments and references to other important decision modeling approaches such as game theory, multiple criteria decision making (MCDM), queuing, and simulation.

INTRODUCTION

“Decision sciences” represents a broad area of research with a common focus on advancing the understanding of decision making processes and improving the quality of decisions, organizational as well as individual. Essentially all types of decisions fall within the realms of the field, but an emphasis is placed on various types of business-related decisions or decisions with an economic dimension. From a methodological perspective, the field contains both behavioral and quantitative modeling research. The former is often closely related to organization theory and psychology, while the latter to a large extent is synonymous with operations research/management sciences (OR/MS), and closely relates to economics, applied mathematics, and statistics. In this entry we restrict our attention to the quantitative modeling (OR/MS) area of decision sciences. The motivation is twofold: first of all, it is arguably the largest area; second, this is where our own backgrounds lie as authors.

Decision sciences research from an OR/MS perspective is usually concerned with improving the quality of decisions. This is done by describing the decision problem in a quantitative model of the real system, then use this model to generate decision alternatives and choose the best among these candidate solutions. The challenges are to model the dynamics and constraints of the underlying system with an appropriate level of detail, and to determine what criteria should be used in assessing what is the best decision. After some reflection most people find this structure intuitively appealing because it fits well with how they make their own decisions (if they are forced to dissect the situation). A set of constraints limits the choices you have and defines the possible alternatives. You then choose between these feasible alternatives

according to some objective function that reflects what your goal is with the decision. In the entry on “Examples of Common Decision Models and Applications,” we will look at several classical models and methods that illustrate variations of this basic model structure. For the remainder of this entry we will take a closer look at the general approach for quantitative decision modeling sketched above. We will then reflect on the past development, and the future opportunities and challenges of the field.

The general approach when using quantitative models is illustrated in Fig. 1. The goal is to find good decisions for some real system. This is very difficult in many situations. Therefore we can choose to replace the real system by a quantitative model. The model seldom provides a complete description of reality, instead it serves as an approximate, simplified version of the real system. However, an advantage is that the quantitative model quite often can be optimized, that is, we can find the best decisions for the simplified version of the real system. In some cases we cannot find the optimal decisions but still some good ones, for example, by using simulation to evaluate some reasonable alternatives. Because the quantitative model does not take all aspects of the real system into account, decisions that are optimal for the model may not be optimal for the real system. However, presuming the model is a valid description of reality, it should capture the essence of the real system at an appropriate level of detail. Decisions obtained from a validated model can be expected to work well also for the real system. Thus if the model is valid, the model decisions can be implemented in the real system with good results. It is often quite difficult to design the quantitative model at the right level of detail. If the model is too simple, it may provide a poor approximation of the real system (i.e., the model has poor validity), and it may be dangerous to use the model as a basis

Fig. 1 Using quantitative models to improve the decision quality.

for generating decisions to be implemented in the real system. On the other hand, if the quantitative model is too complex it may be too difficult to analyze. Thus, it becomes quite useless as a tool for helping the decision maker to make better decisions.

The approach to use quantitative models to analyze and describe reality is a cornerstone in modern science and dates back to the dawn of our civilization. However, the birth of the OR/MS field, with its focus on modeling complex decisions, is often attributed to military activities during World War II. The war effort induced an urgent need to make vital decisions about allocation of scarce resources at a scale never seen before. The U.S. and British military services turned to a large number of mathematicians and other scientists to do research on these decision problems, and to develop scientific methods to help solve them. After the war, the success of these efforts spurred an interest to apply the same approaches to decisions in industry and business. The dissemination was fueled by the fast industrial development following the war, and the fact that many consultants and industry people had come in contact with OR/MS methods during their military service. The fast growth of the OR/MS research field after World War II can also be attributed to the groundbreaking research achievements in OR/MS techniques that attracted talented people into the new field. A stellar example is the Simplex method for solving linear programming (LP) problems, originating with George B. Dantzig in 1947, see Dantzig.^[1] Other important areas where much progress was done early on were dynamic programming, queuing theory, and inventory theory.

Since the early days in the 1940s, the progress of the OR/MS field of decision sciences has been closely connected to the development of the computer and information technology. The revolution in computational power due to the emergence of the digital computer, and later on the emergence of the personal computer, has made it possible to model and solve increasingly complex decision problems. Another important enabler for the development of the field is the tremendous advances in information technology, not least in recent years. Access to an almost infinite amount of information at the press of a button, propels the opportunities for quantitative models to help decision makers evaluate information and decision

alternatives. Hence, the need for quantitative decision models, embedded in user-friendly decision support systems, continues to increase as the tide of information keeps overwhelming the decision makers. From a research perspective, easy access to new and more detailed information in combination with increased computational power creates new interesting challenges and promises an interesting future for the OR/MS area of decision sciences.

Important professional associations, which among other things host some of the most influential conferences and journals in the field, include INFORMS (<http://www.informs.org>), Decision Sciences Institute (<http://www.decisionsciences.org>), and EURO (<http://www.euro-online.org>).

EXAMPLES OF COMMON DECISION MODELS AND APPLICATIONS

In this entry we will look closer at some commonly used quantitative decision models. The ambition is to illustrate how the general model building approach discussed above can be applied in different contexts. The models chosen are classical examples but represent a small sample of the entire field, and should not be construed as an exhaustive representation. For specific examples of OR/MS decision models applied in the library and information sciences area we refer to Kraft.^[2]

Deterministic Models

A deterministic model is characterized by the absence of randomness, meaning that all input values are known with certainty (i.e., correspond to a single outcome with probability 1). A model that incorporates randomness belongs to the class of stochastic models (see the entry on “Stochastic Models”). To exemplify, consider a decision where the customer demand during next week is an important input parameter. If the demand is known to be 50 units it is deterministic. If there is a probability of 0.5 that the demand will be 25 and a probability of 0.5 that it will be 75, the demand is stochastic (or random) with a mean of 50. The advantage of deterministic models over stochastic ones is that they are generally easier to solve, thus, larger problems may be dealt with. Clearly, in most real systems there is some uncertainty present. However, in many situations this uncertainty may be low enough for a deterministic model to be an appropriate approximation. In other situations, the inherent uncertainty may be critical for the decision and must be incorporated into the model, the choice should then fall on a stochastic model.

In this entry we will consider three types of deterministic models: LP models, integer programming (IP) models, and the economic lot sizing model. Examples of stochastic models are found in the “Stochastic Models” entry.

LP models

Linear programming is perhaps the most well known and most widely used decision sciences method to date. It was originally developed by George Dantzig in late 1940s, who proposed the so-called Simplex method for solving large-scale general linear programs. As the name suggests, an LP model is restricted to linear relationships between the decision variables. Programming is, in this case, synonymous with planning, thus LP can be thought of as linear planning.

Generally speaking, an LP model consists of a linear objective function to be maximized or minimized, and a set of linear constraints that limit the decision alternatives. The objective function is a linear equation of the involved decision variables and should reflect how the decision variables impact the overall decision objective. The constraints are also linear equations of the decision variables, describing logical relationships between these variables and how they consume various types of limited resources. Because of its flexibility, the LP approach has been applied to almost any decision situation conceivable, including production planning, scheduling of personnel, investment planning, marketing, logistics, supply chain management, military strategy and tactics, agricultural planning, etc. The most common type of LP application concerns decision problems of allocating limited resources to a number of competing activities in the best possible way (as defined by the objective function). To make the discussion more concrete consider the following example of a classic product mix decision problem.

A production manager who wants to maximize profits is faced with the decision problem of how much to produce of two products A and B during the upcoming planning period. The production process involves three different machines (resources). The times (resource units) to produce a batch of product A and B, respectively, in each of the machines are specified in Table 1. One can also find the available capacity for each of the machines there, and the profit associated with each batch of product A and B sold. Demand is high so we can assume that everything that is produced can also be sold. A restriction is that previous order commitments require that at least 20 batches of product B are produced.

To formulate this decision problem as an LP, the first step is to define the decision variables, which in this case are the amounts of products A and B to be produced.

Table 1 Input data for the product mix example.

Resource	Production time per batch		Available capacity
	Product A	Product B	
1	3 hr	—	150 hr
2	1 hr	2 hr	140 hr
3	2 hr	2 hr	160 hr
Profit per batch	\$1500	\$2000	

X_A = number of batches to produce of product A

X_B = number of batches to produce of product B

Given these decision variables, the goal to maximize total profits (Z) translates into the objective function: $\text{Max } Z = 1500X_A + 2000X_B$.

Turning to the constraints that limit the amount of product A and B that can be produced, the capacity constraints for resource 1, 2, and 3 can be expressed mathematically as:

- (1) $3X_A \leq 150$ (limited capacity in resource 1)
- (2) $1X_A + 2X_B \leq 140$ (limited capacity in resource 2)
- (3) $2X_A + 2X_B \leq 160$ (limited capacity in resource 3)

Similarly, the constraint that at least 20 batches of product B must be produced can be expressed as:

- (4) $X_B \geq 20$ (produce at least 20 batches of product B)

Adding the non-negativity constraints, $X_A \geq 0$ and $X_B \geq 0$ (assuring that the model solution does not suggest negative production) renders the complete LP model of the product mix problem

$\text{Max } Z = 1500X_A + 2000X_B$ (objective function : maximize total profits)

Subject to

- (1) $3X_A + \quad \leq 150$ (limited capacity in resource 1)
- (2) $1X_A + 2X_B \leq 140$ (limited capacity in resource 2)
- (3) $2X_A + 2X_B \leq 160$ (limited capacity in resource 3)
- (4) $X_B \geq 20$ (produce at least 20 batches of product B)
- (5) $X_A, X_B \geq 0$ (non – negativity constraint)

Note that due to constraint^[4], the constraint $X_B \geq 0$ is redundant in this formulation and it is included solely for reasons of completeness.

After formulating the decision model, the challenge is to solve it and determine the optimal decisions. For the current example with only two decision variables the problem can be solved graphically as illustrated in Fig. 2.

Scrutinizing the graphical representation in Fig. 2, the bold lines labeled (1)–(4) correspond to constraints (1)–(4) above when satisfied to equality. The gray shaded area corresponds to the feasible region, where all the constraints are satisfied (including the non-negativity constraint $X_A \geq 0$). The optimal decision must satisfy all the constraints, hence the feasible region defines all decision alternatives of interest. The optimal solution is the feasible solution that maximizes the objective function. The dashed line in Fig. 2 represents the slope (or level) of the objective function, $Z = 1500X_A + 2000X_B$. To maximize Z , we increase X_A and X_B , which corresponds to parallel-shifting

Fig. 2 Graphical solution of the product mix decision problem.

the dashed line in the directions of the arrows depicted in Fig. 2 (mathematically the arrows represent the gradient to the objective function). The optimal solution is the last point on the dashed line which belongs to the feasible region. From Fig. 2 we can see that this corresponds to the corner point of the feasible region where constraint (2) and (3) intersect. Solving the linear equation system defined by constraints (2) and (3) (or by inspecting the graph), the optimal solution $X_A^* = 20$, $X_B^* = 60$ is found. The corresponding objective function value is $Z^* = 150,000$. Hence, the optimal decision obtained from the LP model is to produce 20 batches of product A and 60 batches of product B, which renders a total profit of \$150,000.

Clearly, LP problems of practical interest are considerably larger than the small example studied here (often including thousands or even millions of variables and constraints), which prohibits a graphical solution technique. Instead, these large-scale problems can be solved using, for example, an efficient algebraic technique called the Simplex method. This method utilizes the fact that an optimal solution to an LP problem is always found in a corner point to the feasible region (a consequence of the linearity of all equations). In principle, the method searches through the set of feasible corner point solutions in a structured fashion until a set of optimality conditions are fulfilled, and the optimal solution is found. More details about the Simplex method and other aspects of LP, such as duality and sensitivity analysis can be found in basic OR/MS textbooks such as Hillier.^[3] For more theoretical treatment of the subject one can turn to books like Dantzig^[4-6] and Vanderbei.^[7]

IP models

One limitation with LP models is that the decision variables must be continuous. Hence, it is just a coincidence that the optimal solution to the product mix example above turned out to be in full batches ($X_A^* = 20$, $X_B^* =$

60) rather than fractional. If integer restrictions of the decision variables are added to an LP model, it transforms into an Integer Programming (IP) model. If some variables are allowed to be continuous while others are integer, the model is often referred to as a Mixed Integer Programming (MIP) model.

Solving a problem which contains integer variables is much more difficult than solving a LP model. The reason is that there is no longer a guarantee that an optimal solution is found in a feasible corner point solution. As a result, the number of candidate solutions to investigate increases tremendously. To avoid complete enumeration, which would severely restrict the size of the problems worth considering, much research has gone into finding good solution methods for various kinds of IP problems. One common solution approach is the family of Branch and Bound algorithms. The underlying principle with Branch and Bound is to divide a difficult problem into subproblems that are easier to solve, and then use these subproblems to bound the optimal solution. The subproblems may, for example, be linear programs. For more details about Branch and Bound techniques and other solution approaches for IP models one can turn to, for example, Wolsey.^[8] For a more general introduction to IP models, including examples of formulated problems^[3] is an excellent starting point.

A special case of integer-valued decision variables are binary variables, which are restricted to be either 0 or 1. The binary variables are important in decision modeling because they can be used to describe Yes/No decisions, either or alternatives, fixed charges and stepwise changes. They can also be used for representing general integer variables.

To exemplify the use of binary variables, we return to the product mix example in the “LP Models” entry. After further analysis it turns out that there is a fixed charge of \$1000 associated with starting up production of product A. This start up cost is due to necessary configuration of machinery and special material handling equipment that needs to be acquired in case product A is produced. To incorporate this feature into the decision model, an additional decision variable is needed together with new constraints and a modified objective function.

Definition of the additional (auxiliary) decision variable:

$$y_A = \begin{cases} 1 & \text{if product A is produced} \\ 0 & \text{if product A is not produced} \end{cases}$$

The modified objective function (maximize total profits) that includes the fixed charge associated with producing product A becomes

$$\text{Max } Z = 1500X_A + 2000X_B - 1000y_A$$

The new constraints must assure that y_A is binary and that the contingent decision to produce A or not (modeled by y_A), is aligned with the original decision of how much to produce of A (modeled by X_A). For the formulation, we

define the parameter M to be a very large number, larger than the highest possible production of product A.

- (6) $X_A - My_A \leq 0$ (X_A positive only if $y_A = 1$)
 (7) y_A is binary

The complete formulation of the fixed charge product mix decision problem now amounts to the following MIP model.

$$\text{Max } Z = 1500X_A + 2000X_B - 1000y_A \text{ (maximize total profits)}$$

Subject to

- (1) $3X_A + \dots \leq 150$ (limited capacity in resource 1)
 (2) $1X_A + 2X_B \leq 140$ (limited capacity in resource 2)
 (3) $2X_A + 2X_B \leq 160$ (limited capacity in resource 3)
 (4) $X_B \geq 20$ (produce at least 20 batches of product B)
 (5) $X_A, X_B \geq 0$ (non-negativity constraint)
 (6) $X_A - My_A \leq 0$ (X_A positive only if $y_A = 1$)
 (7) y_A is binary

The versatility of IP models means that they can be used to describe almost any kind of deterministic decision situation with a single objective. Their usefulness in practical applications may however be limited by the computational effort involved in solving large size problems. Still, the situation is continuously improving thanks to increased computer capacity and better solution algorithms. One of the most widely used software packages for solution of large-scale IP (and LP) models is CPLEX, a product sold and developed by the company ILOG.

It may be worth noting that when dealing with reasonably large integer variables it is usually an acceptable approximation to use an LP model and then round the solution to integers (although there is no guarantee that the rounded solution is feasible). However, in case of binary variables this approach is generally not feasible.

Economic lot sizing

Let us now consider a simple nonlinear decision model that has been around for a long time but still is very important in production and inventory management, the so-called classical economic order quantity (EOQ) model.

Consider an inventory location that replenishes its stock of an item from an external supplier. The problem is to determine a suitable batch quantity, that is, to decide on the size of a replenishment order. This decision is mainly affected by two costs. First there is usually a fixed "ordering cost" associated with each replenishment (independent of the batch size). This cost can be due to administrative costs associated with the handling of orders and to costs for transportation and materials handling. The other important cost that needs to be considered is a "holding cost" per unit and time unit. The holding cost includes an opportunity cost for capital tied up in inventory, but may also include other costs that increase with the inventory on hand.

Our simple model assumes that the known demand is constant and continuous. Furthermore, the batch quantity is not changed over time, the whole batch quantity is delivered at the same time, and no shortages are allowed. We shall use the following notation:

- h = holding cost per unit and time unit,
 A = ordering or setup cost,
 d = demand per time unit,
 Q = batch quantity,
 C = costs per time unit.

Clearly, a batch should arrive and be placed in stock just as the previous batch is depleted. The development of the inventory level can therefore be illustrated as in Fig. 3.

We wish to determine the optimal batch quantity Q^* . The relevant costs to consider in the decision model are therefore the costs that vary with the batch quantity Q . We get

$$C = \frac{Q}{2}h + \frac{d}{Q}A$$

The first term represents the holding costs, which we obtain as the average stock, $Q/2$, multiplied by the holding cost h . The average number of orders per unit of time is d/Q , and multiplying by the ordering cost A , renders the ordering costs per unit time in the second term.

It is easy to optimize the cost function. We just set the derivative with respect to Q equal to zero (as one can show that C is a convex function).

$$\frac{dC}{dQ} = \frac{h}{2} - \frac{d}{Q^2}A = 0$$

Solving for Q we get the EOQ:

$$Q^* = \sqrt{\frac{2Ad}{h}}$$

This result was first derived by Harris in Harris^[9] There is also a well-known early paper by Wilson, Wilson,^[10] providing the same result.

Fig. 3 Development of inventory level over time.

As we have discussed in the introduction, it is common to use decision rules that are based on certain simplified assumptions also in settings where these assumptions are not really satisfied. For example, in practice it is common to use the classical lot size formula also in case of stationary stochastic demand. The constant demand d is then usually replaced by the demand forecast. It can be shown that this approximation, in general, works quite well. The considered simple lot size formula has been implemented in an enormous number of inventory control systems. There are also many related models, see, for example, Axsäter.^[11]

Stochastic Models

In many situations, the inherent uncertainty or randomness of decision input information is the main obstacle for making good decisions. Intuitively understanding the consequences of random behavior on the system performance is difficult for most people, including decision makers. This emphasizes the need for quantitative decision models that explicitly incorporate randomness and evaluates its consequences. Describing uncertainty and randomness mathematically involves the use of probability theory and stochastic variables. To make the discussion more concrete and to illustrate the usefulness of stochastic decision models, we will in this entry look closer at the classical newsvendor model, which is the foundation on which many stochastic inventory models are built.

Before turning to the newsvendor model, it is worth emphasizing that the complexity associated with stochastic behavior often prohibits the use of detailed analytical models. In these situations computer-based simulation models may be very useful for evaluating different decision alternatives and analyzing the dynamics of complicated stochastic systems. Particularly, modern discrete event simulation software packages with graphical interface represent a flexible and easy to use decision support tool. For further details on simulation modeling and the use of modern discrete event simulation software, one can turn to Law^[12] and Laguna.^[13] The latter also provides an introduction to analytical modeling of simple queuing systems (see also Hillier),^[3] which represents another important area in stochastic decision modeling.

The newsvendor model

In this entry we consider the classical newsvendor model. In its original form, the problem deals with a newsvendor who can buy copies of a newspaper in the morning for a certain price, and sell them during the day for a higher price. The stochastic demand during the day is known through its probability distribution. The newsvendor is not paid anything for unsold copies of the newspaper.

We shall deal with a slightly more general formulation of the problem and introduce the following notation:

X = stochastic period demand,

$f(x)$ = density of the stochastic period demand,

$F(x)$ = cumulative distribution function of the stochastic period demand, that is, the probability that the demand X is less than or equal to x ,

S = ordered amount,

c_o = overage cost, that is, the cost per unit for inventory remaining at the end of the period,

c_u = underage cost, that is, the cost per unit for unmet period demand.

Let us for a moment go back to the newsvendor interpretation of the problem. The period length is then one day. Assume that the newsvendor pays 25 cents for a copy of the newspaper and sells them for 75 cents during the day. We then have $c_o = 25$, and $c_u = 75 - 25 = 50$. Note that c_u in this case corresponds to the opportunity costs for lost sales.

For a certain demand X the costs are:

$$C(X) = (S - X)c_o \quad \text{if } X \leq S$$

$$C(X) = (X - S)c_u \quad \text{if } X > S$$

Using this we can express the expected costs $C = E\{C(X)\}$ as

$$C = c_o \int_0^S (S - x)f(x)dx + c_u \int_S^\infty (x - S)f(x)dx$$

It is relatively easy to show that the expected costs are minimized when S is chosen so that

$$F(S) = \frac{c_u}{c_o + c_u}$$

This means that the optimal S can be obtained from a very simple decision rule,

$$S = F^{-1}\left(\frac{c_u}{c_o + c_u}\right)$$

The newsvendor model has many important applications, especially when considering ordering and capacity decisions regarding products with a short selling season or product life cycle, for example, in the fashion industry. The model is also closely related to many multiperiod inventory models dealing with an infinite horizon. Assume that there are many periods and associated replenishment opportunities. The overage cost in a period is then the cost to carry a unit in stock to the next period, that is, a holding cost. Similarly, the underage cost can be interpreted as the cost for letting a customer wait to the next period, that is, a backorder cost. For overviews of different types of stochastic inventory models see, for example, Axsäter^[11] and Silver.^[14]

Other Types of Decision Models

So far we have considered two types of decision models, deterministic and stochastic models. For both types of models we have assumed a single decision maker who wants to find the best decision for a considered system as a whole. However, there may also be situations where there are several decision makers interacting (competing or cooperating). If the behavior and responses of these different decision makers are important to understand in order to make good quality decisions, the dynamics need to be incorporated into the quantitative decision model. To analyze game situations where there are several decision makers with different goals, different types of game theoretic models can be used. Such situations are very common in practice.

Let us return to the newsvendor model in “The Newsvendor Model” entry. In this model we only studied a single decision maker. However, it is quite natural to extend the model to include two decision makers. We let the newsvendor have the same role as in “The Newsvendor Model” section. But the newsvendor now buys the newspapers from a supplier with a certain production cost per unit. The supplier can choose the price he wants to charge the newsvendor. In this setting both the supplier and the newsvendor want to maximize their individual profits. What decisions should be taken by the two players? Will the resulting entry be optimal for the system as a whole? It turns out that the answer to the latter question is no. However, if we change the considered “wholesale-price contract” to a “buyback contract” where the supplier pays the newsvendor for left over inventory a coordinated solution may be reached. This means that it is possible to instigate a pricing and contract mechanism so that we can let the supplier and the newsvendor optimize their individual profits and still get a solution that is optimal for the system as a whole.

We refer to Cachon^[15] and Chen^[16] for recent overviews of the literature on coordination and contracts in such systems.

An underlying assumption for all the models we have considered in this entry is that there is a single, well-defined objective for each decision maker, for example, maximizing profits, minimizing costs, etc. However, in many situations the decision maker can be faced with several different objectives that may not be aligned, or may even be in direct conflict. For example, the objective to retain the current workforce may not be aligned with maximizing profits, the objective to maximize environmental friendliness may conflict with an objective to minimize costs, etc. Modeling and analysis of decision problems with multiple (conflicting) objectives is the focus of the multiple criteria decision making (MCDM) area. A basic question when approaching these problems is whether there is a clear order of priority between different objectives or not. An associated question is how to

translate different objectives into a common scale. Monetary terms may not always be the best choice. For more about MCDM one can turn to, for example, Bouyssou.^[17]

CONCLUSIONS

In this entry we have provided a description of the broad area of decision sciences from a quantitative modeling (OR/MS) perspective. An overarching objective with most research in this field is to use quantitative models to improve the quality of decisions. This means that the model is viewed as a tool for helping decision makers to generate, evaluate, and choose good decision alternatives. With this as a starting point, we have explained the conceptual approach underlying the use of quantitative decision modeling. We have also illustrated this general approach by considering some commonly used deterministic and stochastic decision models in more detail. The model types we have discussed include LP, IP, economic lot sizing, and the newsvendor model. We have also briefly commented on extensions and other modeling approaches such as game theory, MCDM, queuing, and simulation.

Looking at the development of the field in recent years, one can conclude that it is in many ways linked to the development and wide spread use of information technology and computers. With the increasing access to vast amounts of information, there is a growing potential for making better decisions that capture the value hidden in the information flow. This accentuates the need for quantitative decision models and decision support systems to help the decision makers sort, evaluate, and process input information into concrete decision alternatives. The increasing amounts of information also suggests more complex and large size models to evaluate, which can be done thanks to the fast development in computer technology, and more efficient solution methods. Altogether one can conclude that this paints a bright and interesting future for the field. However, an important challenge, in order for quantitative decision modeling to reach its full potential, is to bridge the gap between the complex quantitative model and the decision maker. The foundations for those bridges are carefully designed software packages, and easy to use decision support tools.

Abstract

Decision support systems (DSSs) are defined as interactive computer-based systems that aid users in judgment and choice activities. The entry focuses on the core module of DSSs, notably one that directly supports modeling decision problems and identifies best alternatives. It introduces three components of decisions: decision alternatives, preferences, and uncertainty. It presents fundamental components of a DSS: the database management system, the model-base management system, and the dialog generation and management system. It discusses an emergent class of decision-analytic DSSs, based on the sound foundations of probability theory and decision theory. Finally, it reviews issues related to user interfaces to DSSs.

INTRODUCTION

Making decisions concerning complex systems (e.g., the management of organizational operations, industrial processes, or investment portfolios; the command and control of military units; the control of nuclear power plants) often strains our cognitive capabilities. Even though individual interactions among a system's variables may be well understood, predicting how the system will react to an external manipulation such as a policy decision is often difficult. What will be, for example the effect of introducing the third shift on a factory floor? One might expect that this will increase the plant's output by roughly 50%. Factors such as additional wages, machine wear, maintenance breaks, raw material usage, supply logistics, and future demand also need to be considered, however, because they will all affect the total financial outcome of this decision. Many variables are involved in complex and often subtle interdependencies, and predicting the total outcome may be daunting.

There is a substantial amount of empirical evidence that human intuitive judgment and decision making can be far from optimal, and it deteriorates even further with complexity and stress. In many situations, the quality of decisions is important; therefore, aiding the deficiencies of human judgment and decision making has been a major focus of science throughout history. Disciplines such as statistics, economics, and operations research developed various methods for making rational choices. More recently, these methods, often enhanced by various techniques originating from information science, cognitive psychology, and artificial intelligence, have been

implemented in the form of computer programs, either as stand-alone tools or as integrated computing environments for complex decision making. Such environments are often given the common name of *decision support systems* (DSSs). The concept of DSS is extremely broad, and its definitions vary, depending on the author's point of view. To avoid exclusion of any of the existing types of DSSs, we define them roughly as interactive computer-based systems that aid users in judgment and choice activities. Another name sometimes used as a synonym for DSS is *knowledge-based systems*, which refers to their attempt to formalize domain knowledge so that it is amenable to mechanized reasoning.

Decision support systems are gaining an increased popularity in various domains, including business, engineering, the military, and medicine. They are especially valuable in situations in which the amount of available information is prohibitive for the intuition of an unaided human decision maker, and in which precision and optimality are of importance. Decision support systems can aid human cognitive deficiencies by integrating various sources of information, providing intelligent access to relevant knowledge, and aiding the process of structuring decisions. They can also support choice among well-defined alternatives and build on formal approaches, such as the methods of engineering economics, operations research, statistics, and decision theory. They can also employ artificial intelligence methods to heuristically address problems that are intractable by formal techniques. Proper application of decision-making tools increases productivity, efficiency, and effectiveness, and gives many businesses a comparative advantage over their

competitors, allowing them to make optimal choices for technological processes and their parameters, planning business operations, logistics, or investments.

Although it is difficult to overestimate the importance of various computer-based tools that are relevant to decision making (e.g., databases, planning software, spreadsheets), this entry focuses primarily on the core of a DSS, the part that directly supports modeling decision problems and identifies best alternatives. We briefly discuss the characteristics of decision problems and how decision making can be supported by computer programs. We then cover various components of DSSs and the role that they play in decision support. We also introduce an emergent class of *normative systems* (i.e., DSSs based on sound theoretical principles), and in particular, decision-analytic DSSs. Finally, we review issues related to user interfaces to DSSs and stress the importance of user interfaces to the ultimate quality of decisions aided by computer programs.

DECISIONS AND DECISION MODELING

Types of Decisions

A simple view of decision making is that it is a problem of choice among several alternatives. A somewhat more sophisticated view includes the process of constructing the alternatives (i.e., given a problem statement, developing a list of choice options). A complete picture includes a search for opportunities for decisions (i.e., discovering that there is a decision to be made). A manager of a company may face a choice in which the options are clear (e.g., the choice of a supplier from among all existing suppliers). She may also face a well-defined problem for which she designs creative decision options (e.g., how to market a new product so that the profits are maximized). Finally, she may work in a less reactive fashion, and view decision problems as opportunities that have to be discovered by studying the operations of her company and its surrounding environment (e.g., how can she make the production process more efficient). There is much anecdotal and some empirical evidence that structuring decision problems and identifying creative decision alternatives determine the ultimate quality of decisions. Decision support systems aim mainly at this broadest type of decision making, and in addition to supporting choice, they aid in modeling and analyzing systems (e.g., as complex organizations), identifying decision opportunities, and structuring decision problems.

Human Judgment and Decision Making

Theoretical studies on rational decision making, notably that in the context of probability theory and decision theory, have been accompanied by empirical research on whether human behavior complies with the theory. It has

been rather convincingly demonstrated in numerous empirical studies that human judgment and decision making are based on intuitive strategies, as opposed to theoretically sound reasoning rules. These intuitive strategies, referred to as *judgmental heuristics* in the context of decision making, help us in reducing the cognitive load, but alas at the expense of optimal decision making. Effectively, our unaided judgment and choice exhibit systematic violations of probability axioms (referred to as *biases*). Formal discussion of the most important research results, along with experimental data, can be found in an anthology edited by Kahneman et al.^[1] Dawes^[2] provided an accessible introduction to what is known about people's decision-making performance.

One might hope that people who have achieved expertise in a domain will not be subject to judgmental biases and will approach optimality in decision making. Although empirical evidence shows that experts indeed are more accurate than novices, within their area of expertise, it also shows that they also are liable to the same judgmental biases as novices, and demonstrate apparent errors and inconsistencies in their judgment. Professionals such as practicing physicians use essentially the same judgmental heuristics and are prone to the same biases, although the degree of departure from the normatively prescribed judgment seems to decrease with experience. In addition to laboratory evidence, there are several studies of expert performance in realistic settings, showing that it is inferior even to simple linear models (an informal review of the available evidence and pointers to literature can be found in the book by Dawes).^[2] For example, predictions of future violent behavior of psychiatric patients made by a panel of psychiatrists who had access to patient records and interviewed the patients were found to be inferior to a simple model that included only the past incidence of violent behavior. Predictions of marriage counselors concerning marital happiness were shown to be inferior to a simple model that just subtracted the rate of fighting from the rate of sexual intercourse (again, the marriage counselors had access to all data, including interviews with the couples). Studies yielding similar results were conducted with bank loan officers, physicians, university admission committees, and so on.

Modeling Decisions

The superiority of even simple linear models over human intuitive judgment suggests that one way to improve the quality of decisions is to decompose a decision problem into simpler components that are well defined and well understood. Studying a complex system built out of such components can be subsequently aided by a formal, theoretically sound technique. The process of decomposing and formalizing a problem is often called modeling. Modeling amounts to finding an abstract representation of a real-world system that simplifies and assumes as much

as possible about the system, and while retaining the system's essential relationships, omits unnecessary detail. Building a model of a decision problem, as opposed to reasoning about a problem in a holistic way, allows for applying scientific knowledge that can be transferred across problems and often across domains. It allows for analyzing, explaining, and arguing about a decision problem.

The desire to improve human decision making provided motivation for the development of various modeling tools in disciplines of economics, operations research, decision theory, decision analysis, and statistics. In each modeling tool, knowledge about a system is represented by means of algebraic, logical, or statistical variables. Interactions among these variables are expressed by equations or logical rules, possibly enhanced with an explicit representation of uncertainty. When the functional form of an interaction is unknown, it is sometimes described in purely probabilistic terms (e.g., by a conditional probability distribution). Once a model has been formulated, various mathematical methods can be used to analyze it. Decision making under certainty has been addressed by economic and operations research methods, such as cash flow analysis, break-even analysis, scenario analysis, mathematical programming, inventory techniques, and various optimization algorithms for scheduling and logistics. Decision making under uncertainty enhances the above methods with statistical approaches, such as reliability analysis, simulation, and statistical decision making. Most of these methods have made it into college curricula and can be found in management textbooks. Due to space constraints, we do not discuss their details further.

Components of Decision Models

Although a model mathematically consists of variables and a specification of interactions among them, from the point of view of decision making, a model and its variables represent the following three components: (1) a measure of preferences over decision objectives; (2) available decision options; and (3) a measure of uncertainty over variables influencing the decision and the outcomes.

Preference is widely viewed as the most important concept in decision making. Outcomes of a decision process are not all equally attractive, and it is crucial for a decision maker to examine these outcomes in terms of their desirability. Preferences can be ordinal (e.g., more income is preferred to less income), but it is convenient and often necessary to represent them as numerical quantities, especially if the outcome of the decision process consists of multiple attributes that need to be compared on a common scale. Even when they consist of just a single attribute but the choice is made under uncertainty, expressing preferences numerically allows for trade-offs between desirability and risk.

The second component of decision problems is available decision options. Often these options can be enumerated (e.g., a list of possible suppliers), but sometimes they are continuous values of specified policy variables (e.g., the amount of raw material to be kept in stock). Listing the available decision options is an important element of model structuring.

The third element of decision models is uncertainty. Uncertainty is one of the most inherent and most prevalent properties of knowledge, originating from incompleteness of information, imprecision, and model approximations made for the sake of simplicity. It would not be an exaggeration to state that real-world decisions not involving uncertainty either do not exist or belong to a truly limited class. As Benjamin Franklin expressed it in 1789 in a letter to his friend M. Le Roy, "in this world nothing can said to be certain, except death and taxes" (Bigelow.^[3]).

Decision making under uncertainty can be viewed as a deliberation—determining what action should be taken that will maximize the expected gain. Due to uncertainty, there is no guarantee that the result of the action will be the one intended, and the best one can hope for is to maximize the chance of a desirable outcome. The process rests on the assumption that a good decision is one that results from a good decision-making process that considers all important factors and is explicit about decision alternatives, preferences, and uncertainty.

It is important to distinguish between good decisions and good outcomes. By a stroke of good luck, a poor decision can lead to a very good outcome. Similarly, a very good decision can be followed by a bad outcome. Supporting decisions means supporting the decision-making process so that better decisions are made. Better decisions can be expected to lead to better outcomes.

DECISION SUPPORT SYSTEMS

Decision support systems are interactive, computer-based systems that aid users in judgment and choice activities. They provide data storage and retrieval, but enhance the traditional information access and retrieval functions with support for model building and model-based reasoning. They support framing, modeling, and problem solving.

Typical application areas of DSSs are management and planning in business, health care, the military, and any area in which management will encounter complex decision situations. Decision support systems are typically used for strategic and tactical decisions faced by upper-level management—decisions with a reasonably low frequency and high potential consequences—in which the time taken for thinking through and modeling the problem pays off generously in the long run.

There are three fundamental components of DSSs:^[3]

- *Database management system (DBMS)*. A DBMS serves as a data bank for the DSS. It stores large quantities of data that are relevant to the class of problems for which the DSS has been designed and provides logical data structures (as opposed to the physical data structures) with which the users interact. A DBMS separates the users from the physical aspects of the database structure and processing. It should also be capable of informing the user of the types of data that are available and how to gain access to them.
- *Model-base management system (MBMS)*. The role of MBMS is analogous to that of a DBMS. Its primary function is providing independence between specific models that are used in a DSS from the applications that use them. The purpose of an MBMS is to transform data from the DBMS into information that is useful in decision making. Because many problems that the user of a DSS will cope with may be unstructured, the MBMS should also be capable of assisting the user in model building.
- *Dialog generation and management system (DGMS)*. The main product of an interaction with a DSS is insight. Because their users are often managers who are not computer trained, DSSs need to be equipped with intuitive and easy-to-use interfaces. These interfaces aid in model building, but also in interaction with the model, such as gaining insight and recommendations from it. The primary responsibility of a DGMS is to enhance the ability of the system user to use and benefit from the DSS. In the remainder of this entry, we use the broader term user interface rather than DGMS.

Although various DSSs exist, the above three components can be found in many DSS architectures and play a prominent role in their structure. Interaction among them is shown in Fig. 1.

Essentially, the user interacts with the DSS through the DGMS. This communicates with the DBMS and MBMS, which screen the user and the user interface from the physical details of the model base and database implementation.

Fig. 1 The architecture of a DSS.

NORMATIVE SYSTEMS

Normative and Descriptive Approaches

Whether one trusts the quality of human intuitive reasoning strategies has a profound impact on one's view of the philosophical and technical foundations of DSSs. There are two distinct approaches to supporting decision making. The first aims at building support procedures or systems that imitate human experts. The most prominent member of this class of DSSs are *expert systems*, computer programs based on rules elicited from human domain experts that imitate reasoning of a human expert in a given domain. Expert systems are often capable of supporting decision making in that domain at a level comparable to human experts. Although they are flexible and often able to address complex decision problems, they are based on intuitive human reasoning and lack soundness and formal guarantees with respect to the theoretical reliability of their results. The danger of the expert system approach, increasingly appreciated by DSS builders, is that along with imitating human thinking and its efficient heuristic principles, we may also imitate its undesirable flaws.^[5]

The second approach is based on the assumption that the most reliable method of dealing with complex decisions is through a small set of normatively sound principles of how decisions should be made. Although heuristic methods and ad hoc reasoning schemes that imitate human cognition may in many domains perform well, most decision makers will be reluctant to rely on them whenever the cost of making an error is high. To give an extreme example, few people would choose to fly airplanes built using heuristic principles over airplanes built using the laws of aerodynamics enhanced with probabilistic reliability analysis. Application of formal methods in DSSs makes these systems philosophically distinct from those based on ad hoc heuristic artificial intelligence methods, such as rule-based systems. The goal of a DSS, according to this view, is to support unaided human intuition, just as the goal of using a calculator is to aid human's limited capacity for mental arithmetic.

Decision-Analytic DSSs

An emergent class of DSSs known as *decision-analytic DSSs* applies the principles of decision theory, probability theory, and decision analysis to their decision models. Decision theory is an axiomatic theory of decision making that is built on a small set of axioms of rational decision making. It expresses uncertainty in terms of probabilities and preferences in terms of utilities. These are combined using the operation of mathematical expectation. The attractiveness of probability theory, as a formalism for handling uncertainty in DSSs, lies in its soundness and its guarantees concerning long-term performance. Probability

theory is often viewed as the gold standard for rationality in reasoning under uncertainty. Following its axioms offers protection from some elementary inconsistencies. Their violation, however, can be demonstrated to lead to sure losses.^[6] Decision analysis is the art and science of applying decision theory to real-world problems. It includes a wealth of techniques for model construction, such as methods for elicitation of model structure and probability distributions that allow minimization of human bias, methods for checking the sensitivity of a model to imprecision in the data, computing the value of obtaining additional information, and presentation of results (see, e.g., von Winterfeldt^[7] for a basic review of the available techniques). These methods have been under continuous scrutiny by psychologists working in the domain of behavioral decision theory and have proven to cope reasonably well with the dangers related to human judgmental biases.

Normative systems are usually based on graphical probabilistic models, which are representations of the joint probability distribution over a model's variables in terms of directed graphs. Directed graphs, such as the one in Fig. 2, are known as Bayesian networks (BNs) or causal networks.^[8] Bayesian networks offer a compact representation of joint probability distributions and are capable of

practical representation of large models, consisting of tens or hundreds of variables. Bayesian networks can be easily extended with decision and value variables for modeling decision problems. The former denote variables that are under the decision maker's control and can be directly manipulated, and the latter encode users' preferences over various outcomes of the decision process. Such amended graphs are known as *influence diagrams*.^[9] Both the structure and the numerical probability distributions in a BN can be elicited from a human expert and are a reflection of the expert's subjective view of a real-world system. If available, scientific knowledge about the system, both in terms of the structure and frequency data, can be easily incorporated in the model. Once a model has been created, it is optimized using formal decision-theoretic algorithms. Decision analysis is based on the empirically tested paradigm that people are able to reliably store and retrieve their personal beliefs about uncertainty and preferences for different outcomes, but are much less reliable in aggregating these fragments into a global inference. Although human experts are excellent in structuring a problem, determining the components that are relevant to it and providing local estimates of probabilities and preferences, they are not reliable in combining many simple factors into an optimal decision. The role of a decision-analytic

Fig. 2 Example of a BN modeling teaching expenditures in university operations.

DSS is to support them in their weaknesses using the formal and theoretically sound principles of statistics.

The approach taken by decision analysis is compatible with that of DSSs. The goal of decision analysis is to provide insight into a decision. This insight, consisting of the analysis of all relevant factors, their uncertainty, and the critical nature of some assumptions, is even more important than the actual recommendation.

Decision-analytic DSSs have been successfully applied to practical systems in medicine, business, and engineering. Some examples of applications are described in a special issue of *Communications of the ACM* on practical applications of decision-theoretic methods (Vol. 38, No. 3, March 1995). We encourage the readers to experiment with GeNIe,^[10] a development system for decision-analytic DSSs developed at the Decision Systems Laboratory, University of Pittsburgh, available at <http://genie.sis.pitt.edu/>. As these systems tend to naturally evolve into three not necessarily distinct classes, it may be interesting to compare their structure and architectural organization.

- *Systems with static domain models.* In this class of systems, a probabilistic domain is represented by a typically large network encoding the domain's structure and its numerical parameters. The network comprising the domain model is normally built by decision analysts and domain experts. An example might be a medical diagnostic system covering a certain class of disorders. Queries in such a system are answered by assigning values to those nodes of the network that constitute the observations for a particular case and propagating the impact of the observation through the network to find the probability distribution of some selected nodes of interest (e.g., nodes that represent diseases). Such a network can, on a case-by-case basis, be extended with decision nodes and value nodes to support decisions. Systems with static domain models are conceptually similar to rule-based expert systems covering an area of expertise.
- *Systems with customized decision models.* The main idea behind this approach is automatic generation of a graphical decision model on a per-case basis in an interactive effort between the DSS and the decision maker. The DSS has domain expertise in a certain area and plays the role of a decision analyst. During this interaction, the program creates a customized influence diagram, which is later used for generating advice. The main motivation for this approach is the premise that every decision is unique and needs to be looked at individually; an influence diagram needs to be tailored to individual needs.^[11]
- *Systems capable of learning a model from data.* The third class of systems employs computer-intensive statistical methods for learning models from data.^[12–16] Whenever there are sufficient data available, the

systems can literally learn a graphical model from these data. This model can be subsequently used to support decisions within the same domain.

The first two approaches are suited for slightly different applications. The customized model generation approach is an attempt to automate the most laborious part of decision making, structuring a problem, so far done with significant assistance from trained decision analysts. A session with the program that assists the decision maker in building an influence diagram is laborious. This makes the customized model generation approach particularly suitable for decision problems that are infrequent and serious enough to be treated individually. Because in the static domain model approach, an existing domain model needs to be customized by the case data only, the decision-making cycle is rather short. This makes it particularly suitable for those decisions that are highly repetitive and need to be made under time constraints.

A practical system can combine the three approaches. A static domain model can be slightly customized for a case that needs individual treatment. Once completed, a customized model can be blended into the large static model. Learning systems can support both the static and the customized model approach. However, the learning process can be greatly enhanced by prior knowledge from domain experts or by a prior model.

Equation-Based and Mixed Systems

In many business and engineering problems, interactions among model variables can be described by equations that, when solved simultaneously, can be used to predict the effect of decisions on the system, and hence support decision making. One special type of simultaneous equation model is known as the structural equation model (SEM), which has been a popular method of representing systems in econometrics. An equation is structural if it describes a unique, independent causal mechanism acting in the system. Structural equations are based on expert knowledge of the system combined with theoretical considerations. Structural equations allow for a natural, modular description of a system—each equation represents its individual component, a separable and independent mechanism acting in the system—yet, the main advantage of having a structural model is, as explicated by Simon,^[17] that it includes causal information and aids predictions of the effects of external interventions. In addition, the causal structure of a SEM can be represented graphically,^[17] which allows for combining them with decision-analytic graphical models in practical systems.^[17,18]

Structural equation models offer significant advantages for policy making. Often a decision maker confronted with a complex system needs to decide not only the values of policy variables, but also which variables should be

manipulated. A change in the set of policy variables has a profound impact on the structure of the problem and on how their values will propagate through the system. The user chooses which variables are policy variables and which are determined within the model. A change in the SEMs or the set of policy variables can be reflected by a rapid restructuring of the model and predictions involving this new structure.^[19]

Our long-term project, the Environment for Strategic Planning (ESP),^[20] is based on a hybrid graphical modeling tool that combines SEMs with decision-analytic principles. The ESP is capable of representing both discrete and continuous variables involved in deterministic and probabilistic relationships. The powerful features of SEMs allow the ESP to act as a graphical spreadsheet integrating numerical and symbolic methods, and allowing the independent variables to be selected at will without having to reformulate the model each time. This provides an immense flexibility that is not afforded by ordinary spreadsheets in evaluating alternate policy options.

USER INTERFACES TO DSSs

Although the quality and reliability of modeling tools and the internal architectures of DSSs are important, the most crucial aspect of DSSs is, by far, their user interface. Systems with user interfaces that are cumbersome or unclear or that require unusual skills are rarely useful and accepted in practice. The most important result of a session with a DSS is insight into the decision problem. In addition, when the system is based on normative principles, it can play a tutoring role; one might hope that users will learn the domain model and how to reason with it over time, and improve their own thinking.

A good user interface to DSSs should support model construction and model analysis, reasoning about the problem structure in addition to numerical calculations, and both choice and optimization of decision variables. We discuss these in the following sections.

Support for Model Construction and Model Analysis

User interface is the vehicle for both model construction (or model choice) and for investigating the results. Even if a system is based on a theoretically sound reasoning scheme, its recommendations will only be as good as the model on which they are based. Furthermore, even if the model is a very good approximation of reality and its recommendations are correct, they will not be followed if they are not understood. Without understanding, the users may accept or reject a system's advice for the wrong reasons and the combined decision-making performance may deteriorate even below unaided performance.^[21]

A good user interface should make the model on which the system's reasoning is based transparent to the user.

Modeling is rarely a one-shot process, and good models are usually refined and enhanced as their users gather practical experiences with the system recommendations. It is important to strike a careful balance between precision and modeling efforts; some parts of a model need to be very precise, whereas others do not. A good user interface should include tools for examining the model and identifying its most sensitive parts, which can be subsequently elaborated on. Systems employed in practice will need their models refined, and a good user interface should make it easy to access, examine, and refine its models. Some pointers to work on support for building decision-analytic systems can be found in.^[22–25]

Support for Reasoning About the Problem Structure in Addition to Numerical Calculations

Although numerical calculations are important in decision support, reasoning about the problem structure is even more important. Often when the system and its model are complex, it is insightful for the decision maker to realize how the system variables are interrelated. This is helpful not only in designing creative decision options, but also in understanding how a policy decision will affect the objective.

Graphical models, such as those used in decision analysis or in equation-based and hybrid systems, are particularly suitable for reasoning about structure. Under certain assumptions, a directed graphical model can be given a causal interpretation. This is especially convenient in situations where the DSS autonomically suggests decision options; given a causal interpretation of its model, it is capable of predicting effects of interventions. A causal graph facilitates building an effective user interface. The system can refer to causal interactions during its dialogue with the user, which is known to enhance user insight.^[26]

Support for Both Choice and Optimization of Decision Variables

Many DSSs have an inflexible structure in the sense that the variables that will be manipulated are determined at the model-building stage. This is not very suitable for planning of the strategic type when the object of the decision-making process is identifying both the objectives and the methods of achieving them. For example, changing policy variables in a spreadsheet-based model often requires that the entire spreadsheet be rebuilt. If there is no support for that, few users will consider it as an option. This closes the world of possibilities for flexible reframing of a decision problem in the exploratory process of searching for opportunities. Support for both choice and optimization of decision variables should be an inherent part of DSSs.

Graphical Interface

Insight into a model can be increased greatly at the user interface level by a diagram representing the interactions among its components (e.g., a drawing of a graph on which a model is based, such as in Fig. 2). This graph is a qualitative, structural explanation of how information flows from the independent variables to the dependent variables of interest. Because models may become very large, it is convenient to structure them into submodels, groups of variables that form a subsystem of the modeled system.^[2,7] Such submodels can be again shown graphically with interactions among them, increasing simplicity and clarity of the interface. Fig. 3 shows a submodel-level view of a model developed in our ESP project. Note that the graph in Fig. 2 is an expanded version of the *Teaching Expenditures* submodel in Fig. 3. The user can navigate through the hierarchy of the entire model in her quest for insight, opening and closing submodels on demand. Some pointers to work on user interfaces of decision-analytic systems can be found in Wang,^[25] Druzdel^[27,28] and Wiecha.^[29]

CONCLUSION

Decision support systems are powerful tools integrating scientific methods for supporting complex decisions with techniques developed in information science and are gaining an increased popularity in many domains. They are especially valuable in situations in which the amount of available information is prohibitive for the intuition of

an unaided human decision maker, and in which precision and optimality are of importance. Decision support systems aid human cognitive deficiencies by integrating various sources of information, providing intelligent access to relevant knowledge, aiding the process of structuring, and optimizing decisions.

Normative DSSs offer a theoretically correct and appealing way of handling uncertainty and preferences in decision problems. They are based on carefully studied empirical principles underlying the discipline of decision analysis, and they have been successfully applied in many practical systems. We believe that they offer several attractive features that are likely to prevail in the long run as far as the technical developments are concerned.

Because DSSs do not replace humans but rather augment their limited capacity to deal with complex problems, their user interfaces are critical. The user interface determines whether a DSS will be used at all and, if so, whether the ultimate quality of decisions will be higher than that of an unaided decision maker.

Demand-Driven Acquisition/Patron-Driven Acquisition

Michael Levine-Clark

Penrose Library, University of Denver, Denver, Colorado, U.S.A.

Abstract

Demand-driven acquisition (DDA), also commonly referred to as patron-driven acquisition (PDA), is a process used by libraries to provide a large pool of content to their users while only paying for portions of that content at the point of use. Typically, records for that content are displayed in the library's catalog or discovery system, and when patrons find those records and access that content, a purchase or temporary lease of that particular title is triggered. DDA has most commonly been used for e-books, but it has been used for other formats as well.

INTRODUCTION

Demand-driven acquisition (DDA) is an overarching term for a number of different models that libraries can use to provide content to their users and pay for that content at the point of use. Patron-driven acquisition (PDA) is often used synonymously with DDA but, for the purposes of this article, is considered to be a broader term. PDA in this broader sense refers to something that libraries have always done—respond to the suggestions of their users. In this sense, a librarian purchasing a book because of a patron request or adjusting an approval plan because of an analysis of usage is practicing PDA. DDA is a subset of PDA in which those patron-driven decisions are pushed to the point of demand; when a patron needs a book (or some other type of resource), the library acquires that content for her, ideally in an unmediated way.^[1]

There are a number of different models for DDA, which are described in the following sections, but all allow libraries to provide a larger pool of content to their users than would be possible under traditional models. Instead of acquiring books that may or may not ever be used, a library can provide access to a broader “consideration pool” of titles and pay for only those that get used.

RATIONALE FOR DDA

DDA solves a supply and demand issue for libraries: there are far more books published than even the best funded libraries can purchase, and of the books purchased by libraries, many get little or no use. The *Library and Book Trade Almanac* reports that in 2014, 200,768 titles were published in the United States alone.^[2] The International Publishers Association (IPA) has an even higher figure for 2013, with 304,912 titles (including new editions of previously published works) published in the United States. The IPA reports a figure of 444,000 for China and 184,000 for the United Kingdom. Many other countries

publish more than 50,000 titles a year, and even relatively small countries such as Slovenia publish more than 3,000 volumes.^[3] Even the biggest libraries can afford to purchase only a fraction of this annual publishing output. Librarians traditionally have done the best they could to build collections that made sense for local curricular and research needs but have always needed to make choices about which books to purchase. Meanwhile, numerous studies have shown that large portions of academic library monograph collections do not get used.^[4] DDA allows libraries to provide access to a wider range of this massive publishing output by reallocating some of the funds that would traditionally be spent on these unused titles.

DDA can be used to broaden the collection by providing access to more titles, from more publishers, across a wider range of subjects. If libraries do not need to make a decision about what book to buy until the point of use, they can give their users a larger choice of titles. In theory, a library could provide access to many more titles, while spending the same amount of money as in the past, thus creating a broader and deeper collection.

DDA can also be used to save money. A library could decide to select the same number of titles as it used to under traditional acquisition models, but instead of buying them, make them available for potential use and purchase. Assuming similar usage patterns, not all of these titles would be used and the library would spend less overall on monographs.

In reality, libraries have used DDA both to save money and to broaden the collection. They have provided access to more titles than they would have purchased in the past but have spent less overall.^[5]

DEVELOPMENT OF DDA

An early version of DDA was developed by the Colorado Alliance of Research Libraries, which ran a consortial-level DDA program for netLibrary e-books from 1999 to

2005. Participating libraries loaded records for e-books into their catalogs, and the consortium agreed with netLibrary to allow one free use of any book in the consideration pool, with purchase on the second use. The consortium paid 155% of list price to share purchased titles across the entire group. In theory, having a purchase happen only on a second use meant that titles with limited demand would not be acquired, but in practice, the consortium found that many books with just two very brief uses were purchased. Ultimately, because of the low threshold for purchase, this model proved unsustainable.^[6]

A more enduring model of DDA was developed by Ebooks Corporation, which eventually became known as Ebooks Library (EBL), based on conversations with Alison Sutherland, a librarian at Curtin University in Australia, in 2001 and Jens Vigen, from CERN, in 2002. Sutherland approached Ebooks Corporation with the idea of purchasing e-books on demand. Vigen followed up a year later with the concept of pay-per-view rental access for e-books as an alternative to interlibrary loan (ILL). Out of these conversations, EBL launched in 2004 with a model that paired a 5-min free browsing period in the e-book, with paid short-term loans (STLs), and purchasing after multiple paid uses.^[7] With this model, libraries did not buy books with very little use, because these uses either triggered a relatively cheap STL or if they were short enough, led only to a free browse of the book. Ultimately, this model proved successful, and e-book aggregators such as ebrary and EBSCO (which subsumed the netLibrary brand) adopted it as well.

DDA was used by a relatively small number of libraries in its early years, with a big uptake around 2010–2012. Ingram, through the MyiLibrary e-books aggregator and Coutts approval vendor, set up its four initial DDA programs in 2008. By the end of 2009, Ingram managed 17 programs. In 2010, 17 more were added, including their first consortial DDA program. DDA expanded dramatically in 2011, with 31 new programs, including the first program to include DDA for print. In 2012, Ingram added 39 programs.^[8] Meanwhile, YBP Library Services, the other major academic library approval vendor, began the development of DDA services with aggregator partners in 2010. Many of these customers had already worked with aggregators directly and approached YBP for assistance in integrating this new method of collection development into their existing acquisitions workflow. In 2011, YBP implemented 63 DDA programs for customers with either EBL or ebrary. In 2012, YBP expanded to include EBSCO and added 63 more DDA programs, some of which used all three e-book aggregators.^[9]

COMMON THEMES OF DDA

There are many different models of DDA, but all of them allow purchase of content at the point of use. Most

programs have some aspect of free discovery, which allows users to discover whether content is worthwhile before triggering a purchase. In some programs, there is an option to pay for temporary access, allowing payment based on a brief usage of the material. And all programs have an ultimate option to purchase content, generally after passing through the free discovery and temporary paid access stages.

Free discovery works in different ways but is intended to prevent unintended purchase of content that might not actually be relevant to the user. In some cases, this free discovery period is time based, with usage under 5 or 10 min being free. In others, it is based on usage of some portion of the book, with the front or back matter free, for example. Another model allows for the first or second usage to be entirely free but triggers a purchase after the second or third usage. With this last option, there could still be multiple “accidental” uses of material that is not truly relevant to the user.

Temporary access, most commonly offered in the form of an STL, allows the library to pay for access for a day, a week, or some other brief period, based on the assumption that in many cases a patron will use a book once or twice and that then the library will never have demand for that particular title again. Rather than paying list price for a book that may never be used again, a library can provide immediate and temporary access for a fraction of list price. Libraries can generally choose how many STLs to offer, with the understanding that a higher number of STLs will mean a greater emphasis on access to content and less on ownership.

In all cases, there is an option to purchase content through DDA, though in relatively few cases a library can implement DDA with only STLs. For some libraries, the goal of the program is to use patron input to build a permanent collection. For others, the goal is to provide as wide a range of content to the user as possible, and ownership is less important. Libraries that wish to emphasize collection building will likely want to trigger purchase sooner in the process (and some do away entirely with STLs, purchasing on the first use).

DDA MODELS

Broadly speaking, there are four basic models for DDA, with wide variation within them. None of these are perfect, and there are risks and rewards for each. *Demand-Driven Acquisition of Monographs: A Recommended Practice of the National Information Standards Organization* provides a detailed overview of these models, with some exploration of how they might fit into the goals of a particular library choosing to implement DDA.^[10]

The oldest model, used originally by netLibrary with the Colorado Alliance of Research Libraries, is relatively simple in concept. The first several uses of an item are free

and then the next use triggers a purchase. For the Colorado Alliance, this was one free use with a purchase on the second. Ebrary and MyiLibrary both used this netLibrary model when they first adopted DDA. Though easier to implement, this model can lead to purchase of content that may not be needed, since presumably a patron could spend one second looking at a book and that would count toward purchase.

There are several examples of the risks involved with the netLibrary model, one of which occurred with the Colorado Alliance program. In this example, there was an assignment related to bananas in a geography class at the University of Colorado Boulder. Students searched within netLibrary and found e-books, whether relevant or not, that mentioned the word “banana.” Because the program committed the Colorado Alliance to purchase books on the second use, regardless of length, the Alliance quickly purchased all of the books in netLibrary’s collection with the word “banana.”^[11] It is worth noting that a free discovery period would have prevented this from happening. The University of Iowa, one of the early adopters of DDA with ebrary in 2009–2010, reported rapidly overspending their budget when using a similar model but with ten uses of any length before a purchase was triggered. After just a few months, Iowa had to cut back the number of titles in their consideration pool dramatically.^[12]

A more complex model is the one developed by EBL and eventually adopted by ebrary and others. This model involves the free discovery period of 5 min (10 min for ebrary), STLs, and a purchase. Libraries can configure these as they wish, using more or fewer STLs before purchase. A library wishing to emphasize access can have more STLs, while one wishing to emphasize purchase can have fewer. The book will be purchased after that number of STLs has been surpassed. Doug Way and Julie Garrison showed that in early implementations of this model, it was cheaper overall to have more STLs prior to purchase.^[13]

After wide adoption of the EBL model by libraries, publishers became concerned about the impact of STLs on their revenue. With multiple STLs before purchase, many libraries were paying for a small number of STLs of e-books but never purchasing these titles. Overall, publishers saw declining sales and responded in 2014 and 2015 with increases in the prices charged for STLs. A few publishers also pulled front list titles from STL programs.^[14] It is likely that other publishers quietly pulled content from DDA programs entirely. At this point, it is unclear what the full impact of this change will be.

ProQuest Ebooks (which includes EBL, ebrary, and MyiLibrary) has recently introduced a rent-to-own model, called “Access-to-Own,” in which STLs count toward purchase. The model was developed to address the concerns about STL costs and provides a trade-off of sorts: in return for accepting higher STL rates, libraries benefit by being able to apply those STL fees toward the purchase cost. Publishers benefit by having higher STL costs for

titles with low use and an easier path to a sale of the book for higher-use titles.^[15]

A different model, used by several publishers on their own platforms, is evidence-based acquisition (EBA), also known as evidence-based selection (EBS). Under EBA, a library commits a certain amount of money to a publisher and agrees to buy content from that publisher at the end of the year based on an evaluation of usage data. The publisher then makes available some agreed-upon amount of content for the library’s patrons to choose from throughout the year. EBA allows a publisher to offer DDA without having to develop the infrastructure that the more complex aggregator-based models require.^[16]

There are risks and rewards for both publishers and libraries under EBA. Because EBA relies on a library to guarantee a certain amount of money to a publisher up front, a library runs the risk of having to purchase unused or little used content at the end of the year. On the other hand, publishers run the risk of libraries gaining access to a large amount of heavily used material for a relatively low price. Negotiating a reasonable price and mix of content up front is important for both partners in such a program.^[16]

DDA FOR VIDEO

Most DDA programs thus far have involved e-books, but an increasing number of vendors are offering DDA for streaming video. Alexander Street offers both an EBA version and one in which purchases are triggered at the point of use.^[17] Kanopy also has a DDA model and reports that more than 1500 institutions have adopted it globally.^[18] DDA has allowed libraries to expand their video collections dramatically.

DDA FOR PRINT MONOGRAPHS

Some libraries have developed DDA programs for print monographs, often in conjunction with an e-book DDA program. The University of Vermont developed a print-only DDA program in 2007 in which they loaded records from three major publishers into their catalog, allowing patrons to identify unowned books and then request a purchase. They expanded this program to include e-books in 2011.^[19] Though DDA for print is less common than it is for e-books, other libraries, such as the University of Arizona, have implemented DDA programs that combine e-books and print books.^[20]

DDA for print monographs (or any other tangible formats) is complicated by the fact that the materials selected will not be immediately available to the user. Print DDA programs require clear messaging to the user that the content is not available for immediate use and may take some time to be delivered. Further, because it has to be

delivered to the user, it is crucial to gather accurate data about the patron. DDA for print also requires development of forms that can be populated with bibliographic data about the item being ordered. Once data about the patron and item have been gathered, the library must order the book, determine a reasonable shipping time and process, and then deliver the item to the patron. While it is not as easy to implement, print DDA has been successful in the relatively small number of libraries with it in place.

CONSORTIAL DDA

Libraries often use consortia to negotiate substantial discounts for bulk purchasing, and based on that success, many have tried to build consortial DDA plans. The earliest, as noted previously, was the netLibrary plan for the Colorado Alliance of Research Libraries. A more recent success has been a program with EBL for the Orbis Cascade Alliance. Developed in 2010, this program uses a multiplier model to provide shared access to e-books across the consortium. While STLs are charged at the same rate as they would be for a single institution, the cost of purchasing the e-book is calculated at five times the list price and the consortium then shares perpetual access rights.^[21] The multiplier model has become common across many consortia. One of the consortia using this model, the Colorado Alliance of Research Libraries, has questioned whether shared ownership makes sense for DDA. Early data from the Colorado Alliance project suggest that by some measures it would have been cheaper for libraries to do DDA on their own.^[6] The Colorado Alliance experience points to an essential contradiction in consortial DDA programs: while consortial purchasing relies on a group purchase of shared content to lower overall pricing and is thus geared toward ownership of the same content across the group, DDA is predicated upon purchase based on use, and use of a given title is often not the same across institutions.

Novanet, a consortium in Nova Scotia, developed a DDA program in 2011 that uses a different model in which the consortium purchases shared access to the e-book for list price but pays for another copy of the e-book after reaching a certain threshold of usage.^[22] This model solves the problem that the Colorado Alliance faced, in which the consortium paid a multiplier for e-books that ultimately had very little subsequent use. In the Novanet model, only higher-use books trigger a multiplier on the list price.

THE CONSIDERATION POOL

In all DDA programs, there must be a consideration pool, a set of titles available for potential discovery and purchase. Libraries can choose to carefully curate the titles

available in the consideration pool or can open it very broadly. Decisions about the size and scope of the consideration pool are linked both to financial pressures and the vision of the library about the type of collection DDA is intended to support.

With a smaller consideration pool, a library has less risk of overspending a budget. Some libraries have opted to limit the pool by publisher, by publication year, or by subject. The pool can be limited on the front end, as titles are published, or later on as libraries choose to remove them from view.

Similarly, libraries might choose to limit the scope of a consideration pool out of concerns for quality or curricular match. In this case, some of the same criteria might be employed but for a different purpose. Libraries opting to limit the size of the pool for quality reasons might leave older books in the pool but would be careful to include only books that match other predetermined needs. Some libraries using YBP or Coutts to manage DDA do so because of the capabilities those companies have to profile for academically relevant books.

Other libraries have taken a much broader approach to profiling and have embraced a philosophy that users know best what they need. At the extreme end of this viewpoint, a library might make all titles available in a consideration pool, whether academically relevant or not, with the assumption that in some cases popular material can serve a scholarly purpose. More likely, libraries with a broad approach to the consideration pool will consider a wider range of subjects than they would have under a traditional speculative purchasing program. For example, a library at a university without an architecture program would typically buy a handful of architecture books to support art history but would ignore most books on this topic. With DDA, this same library might choose to make available a wide range of architecture books for the same purpose.

In reality, most libraries have needs to both limit and expand the consideration pool. They will want to expand it to include subjects that were not traditionally purchased at their institutions but will need to consistently or periodically reshape the pool to exclude content for budgetary purposes.

RISKS

There are some significant risks for both libraries and publishers with DDA. With traditional purchasing, libraries knew that books that they acquired would be there in perpetuity for their patrons. They did not have to worry about titles going out of print because they were securely on their shelves. With DDA, while libraries do not have to expend scarce resources on purchasing titles that may not be in use and overall have more titles available to their users than would have been possible traditionally, they run the risk of those titles no longer being available at the

point of need. Publishers occasionally either pull content in whole or in part from e-book aggregators or change prices enough that libraries need to remove some titles from the consideration pool, making them unavailable to users at the point of need.

The risk of DDA for publishers has already become clear and resulted in the rising costs of STLs. Concurrent with the rise of DDA and STLs, publishers have seen sales of books to academic libraries decrease, making it possible that some types of books may be too risky to publish.^[23] While this decline in monograph sales to academic libraries has been linked to increasing adoption of DDA and STLs, it has also been coincidental to general declines in purchasing power for libraries. Nonetheless, the predictability that library sales traditionally gave to publishers is gone, and DDA is at least partially responsible.

PRESERVATION

While there is risk inherent in DDA, there is opportunity as well. Traditionally, academic libraries have concentrated purchasing at the point of publication, with only moderate addition of older titles to the collection. Because of the relatively small print runs of scholarly monographs, once these copies sold to libraries and then the title went out of print, it was hard to find older books for purchase. DDA allows libraries to extend the point of purchase well past the point of publication, but to do so requires that those titles still be available for purchase.

As consideration pools grow and become ever more important means of providing access to content, it is essential that libraries be confident that the not-yet-purchased content will still be there at some point in the future. Tools such as Portico and CLOCKSS preserve content but are geared toward providing libraries with access to the material that they have already paid for, not the content they might someday wish to pay for. A long-term preservation solution might help mitigate risk for libraries and publishers. Libraries would have the confidence that content would be available whenever their users needed it and publishers might be able to rely on sales far into the future.

INTERLIBRARY LOAN

Libraries have traditionally used ILL to provide patrons with temporary access to materials not in the collection. ILL was cheaper for libraries than purchasing a book or was the only way of supplying a book that was out of print. ILL allows libraries to share resources widely and means that low-use titles do not need to be acquired by every library. Some of the earliest examples of DDA occurred when libraries began purchasing titles requested

through ILL, either because purchasing those titles was cheaper than ILL or because they met some criteria to be added to the collection.^[24] This function is largely for print monographs or other tangible materials.

On the e-book side, STLs can serve much the same function as ILL, providing temporary access to materials not in a library's collection. Publishers were willing to experiment with STLs at least in part because of this potential to serve an ILL-like function while providing some additional revenue.^[23] Unlike ILL, which is staff intensive and does not provide a user with instant access to requested material, STLs could provide a better patron experience than ILL of an e-book.^[25]

CONCLUSION

DDA is a means of providing access to content that libraries purchase at the point of use. By linking purchase to demand, DDA allows libraries to provide access to far more content than was possible traditionally. While mostly used for e-books, DDA has been used for print monographs and for streaming video as well. It is closely linked to ILL purchasing and could replace some aspects of ILL.

DDA has been around since 1999 but was first widely adopted around 2010. Since then, the models have been evolving as publishers and libraries get used to the cost structures and the risks. Though the models will likely continue to shift, DDA as a concept appears to be here to stay. Libraries and publishers need to work together to make sure that it is sustainable for both parties.

Denmark: Libraries, Archives, and Museums

Jens Thorhauge

Jakob Heide Petersen

Danish Agency for Libraries and Media, Copenhagen, Denmark

Ole Magnus Mølbak Andersen

Danish State Archives, Copenhagen, Denmark

Abstract

The authors provide an overview of the modern development of libraries, archives, and museums in Denmark. Topics covered include: National, public, academic, special and school libraries as well as the Danish Agency for Libraries and Media, the State Archives, regional archives, university archives, the Heritage Agency of Denmark, and three major types museums: natural history, art, and cultural heritage. The legal framework for these institutions is detailed. The authors also describe the role of professional associations and the development and professional education in these three fields. Finally, recent trends and issues are discussed with a focus on digital projects.

INTRODUCTION—FACTS ABOUT DENMARK

Denmark (Fig. 1) is a northern European state and part of the Scandinavian cultural community. The country has been an independent kingdom for more than 1000 years with variable frontiers. Since 1920, the frontiers have been permanent with an area of 43,094 km². The population in 2006 was 5,427,459. The capital is Copenhagen.

Denmark is a fertile low-lying country, which for the most part is cultivated. Agriculture was the dominant trade until about 1850 when industrialization began. Today, the majority of the population live in towns and are employed in industry, commerce, and service. Denmark's gross national product is one of the highest per capita in the world, as is its rate of taxation. Its social and healthcare system is publicly funded, and education is free all the way to the highest university level.

The Danish constitution is based on the Constitution of the Kingdom of Denmark, most recently revised in 1953. It goes back to the Constitution of 1849, which ended a constitution of absolute monarchy introduced in 1660. In 1849, a parliament with two chambers was introduced. Today, Denmark has a one-chamber parliament and a multiparty system. Since 1972, it has been a member of the European Community, and since 1992, of the European Union.

LIBRARY AND INFORMATION SYSTEMS AND SERVICES

The First Libraries and Absolute Monarchy

As in other European countries, the earliest libraries were established in monasteries in the Middle Ages. Later,

libraries were set up at the cathedral schools which from about 1100 were established in connection with a number of cathedrals, where priests were also educated till the University of Copenhagen was founded in 1479 and with it the first Danish university library. The first Danish book had been printed in 1482.

Ten years before the absolute monarchy was introduced in Denmark, King Frederic the Third had started building up a library and cabinet of curiosities. These collections formed the basis of those in The Royal Library, The National Museum, and the Danish National Gallery. In 1697, legal deposit of all printed material was introduced. The Enlightenment in the 1700s left distinct traces in Denmark. In 1775, P.F. Suhm, professor at the University of Copenhagen, opened his library of 100,000 volumes to the public. Twenty years later, the Royal Library opened its collections to the public. Government archives suggest definite moves toward systematic registration as the country became more centralized under the absolute monarchy. The Royal Cabinet of Curiosities became the Royal Art Museum in 1842 and included art as well as other museum objects.

General compulsory education was introduced in 1814 where the country, following the national bankruptcy of the previously year, started to expand in relation to education and culture. Today, the Folkeskole's (municipal primary and lower-secondary school) educational program runs for 9 years.

Democracy and public libraries

The absolute monarchy was abolished peacefully in 1849, and the royal collections went to the state. Art was separated and the Danish National Gallery established. Several

Fig. 1 Map of Denmark.

Source: CIA World Factbook (<https://www.cia.gov/library/publications/the-world-factbook/geos/da.html>).

art-historical collections were gathered together in what is today The National Museum. One of these collections was the collection of antiquities, which was made publicly available in 1819. Around this time, the first public libraries were established on the initiative of enlightened citizens, often organized in associations.

With the emergence of the labor movement in 1870 came a movement in favor of public enlightenment. This resulted in reading societies in the towns that built up libraries. In 1882, the State began awarding grants to chapbook collections. In 1900, A.S. Steenberg published a book on the organization and design of libraries. The book was based on his studies of English and American free public libraries. This book became the basis for the subsequent structure of a modern library system. In 1909, the State established an office for the support of library initiatives with Steenberg as its leader, and in the same year, the Royal Library's chief librarian, H.O. Lange, published his ideas of a coherent library system based on regional libraries. In 1920, the first act on public libraries was passed, based on these thoughts, and in that same year, the Book Collection Office became the State Inspectorate of Public Libraries with Thomas Døssing as director and driving force of the systematic development of public libraries all over the country.

A librarian training course was established in 1918 as a mixture of practice and theory. The Royal Library School was established in 1956. In 1999, the school gained university status and the previous education programs were

replaced by bachelor's and master's programs and the possibility of Ph.D. studies.

The Royal Library (Fig. 2), the University Library and the libraries at the Technical College of Denmark and the Royal Veterinary and Agricultural University were the only academic libraries until 1902 when the State and University Library in Aarhus was founded to serve the public outside the capital. In 1928, Aarhus University was founded, and the State and University Library (Fig. 3) became its library. During the last third of the twentieth century, a number of universities and university colleges were established, and the national museum collections were supplemented by professionally run art and cultural-historical-museums in many towns.

The welfare state and the expansion of public libraries

During the interwar and postwar periods, public libraries followed the classical model with the loan of books and the administration of reading rooms as central activities. The task was to establish libraries wherever the need arose and make sure that they were run professionally. In this period, many public libraries became a driving force in study circle activities. With the 1964 amendment to the law, public libraries were made mandatory in all municipalities; cultural activity was included in the legislation, and libraries geared up to meet the educational boom that arrived with prosperity and the baby boom. In 1970, a municipal reform resulted in merging the small rural districts. This provided the basis for a sustained professionalization of the public libraries. In 1983, the responsibility for local public library service was entrusted to the municipalities. At the same time, the financing of public libraries changed from government subsidy to block grants with the municipalities' free right of disposal as a basic principle.

The last major wave of change arrived with IT development. The first initiatives within cataloging came around 1970 with OPAC (Online Public Access Catalog) as their goal. The breakthrough of the Internet in the mid-1990s brought with it a challenge to change all libraries into hybrid libraries. Home pages and Internet access for the public appeared in the latter half of the 1990s. It became obligatory with the Act regarding library services in 2000 that established free access to a Web-based National Union Catalog and mandated broad media access through public libraries.

Throughout the twentieth century, the public library system was consolidated with regional libraries in the counties, libraries in all municipalities, and more branches in larger towns. But many libraries were still owned by associations, and only with the revision of the library act in 1964 was municipal library service made obligatory. In 1983, full responsibility for the local public library was

Fig. 2 The Royal Library in Copenhagen.

transferred to the municipality. But from the beginning of the century the State maintained a firm involvement in the development of the libraries.

Legislation

Library activities have been regulated by legislation since 1920; the law is changed at regular intervals. The latest act dates from the 2000, Act regarding library services (I 78, 2000) (English version: <http://www.bs.dk/publikationer/english/act/index.htm>). The Act addresses public libraries, regional libraries, government libraries, and government obligations. The stated objective of library service is to “promote information, education, and cultural activity.” The means are making books and other relevant media available, including Internet access. The public library is open and available to everyone for the loan of materials. All services are free. Public libraries must cooperate with school libraries, which are obligatory in municipal schools and are run as part of the school activity. All municipalities are obliged to provide library service for both children and adults. The State is responsible for the national bibliography and for the union catalog, which is made available via the Internet. The State also pays for regional library service. Together with the State and University Library, the regional libraries are a “superstructure” for the public libraries and handle a number of tasks in relation to procurement of materials, advice, and competency development in the libraries.

The law provides a legal framework that deals with the way libraries should perform their tasks in the information society. It emphasizes that there are media other than print and defines the conditions for giving access to the Internet. For state libraries, including university libraries, a condition for receiving subsidies is that they must participate in interlibrary loan cooperation free of charge.

Legal deposit was introduced in 1697. In 1998, the act on legal deposit was changed so that the deposit obligation included not only printed material but also other media, such as e-publications, videograms, databases, film, and radio and TV broadcasts. The 2005 revision of the law includes harvesting the Danish part of the Internet. Legal deposit of printed material is shared between the two national libraries, the Royal Library and the State and University Library. The latter is responsible for the National Newspaper Collection, radio and TV programs, and film produced with a right to public viewing.

Public Lending Right Remuneration is distributed as a culture subsidy to Danish authors whose works are available at public and school libraries. Public Lending Right Remuneration has been paid out since 1946; Denmark was the first country in the world to introduce this subsidy scheme. The principles are stated in the Act on Public Lending Right Remuneration.

The legal framework for the school library can be seen in The Folkeskole (2) where it is determined that a school

library must be established in every Folkeskole and that these must function as pedagogical service centers.

National Library and Information Services

The Danish Agency for Libraries and Media, which operates under the Ministry of Culture, is the central government organ for libraries and media. The Agency handles a number of administrative tasks related to the libraries, including administration of the Act regarding library services. Likewise, it deals with development tasks in association with the libraries' activities and administers a number of subsidies within the library area.

The Agency was founded in 1920 as the State Inspectorate of Public Libraries with tasks related to the public libraries. In 1986, it merged with The Office of the National Librarian, thereby being allocated coordinating tasks regarding the research libraries. In 1997 this office gained status as an agency entitled Danish National Library Authority. In 2008 the Agency merged with The Danish Agency for Media and gained its present name.

The Danish Agency for Libraries and Media, performs tasks that in other countries might belong to the national library. It is responsible for

- The national bibliography.
- Standards, including cataloging rules etc.
- National bibliographic databases, DanBib and Bibliotek.dk (library.dk).
- The national distribution scheme for interlibrary lending.
- Financing the regional library service.
- Handling performance contracts with 16 regional libraries, which in 2010 will be reduced to six.

The regional libraries act as central repositories for materials, advise smaller libraries and are responsible for professional development.

The Danish Agency for Libraries and Media, is secretariat for Denmark's Electronic Research Library, which is a collaboration between more than 200 special and academic libraries and handles licenses for e-resources to Danish educational and university libraries. The division of work between the Agency and the libraries means that the agency is responsible for the infrastructure, while the municipalities and research and education institutions are responsible for the actual running of the libraries. Central to the infrastructure is the union database, DanBib, which started in 1994 and registers all Danish library records. DanBib forms the basis of bibliotek.dk, the libraries' common public portal that opened in 2000. There one can search for and request any titles in a Danish library. Projects are in progress concerning the establishment of a common data well with bibliotek.dk and databases with e-resources for the purpose of establishing integrated search.

The Agency is responsible for coordinating library collaboration and ensuring national development of the libraries. This happens via subsidies for development projects and professional development. The Danish Agency for Libraries and Media has entered into a contract with Danish Bibliographic Center, a limited company owned mainly by the Danish state and municipalities, for the preparation of the national bibliography and the running of DanBib and bibliotek.dk. The Royal Library in Copenhagen and The Danish State and University Library in Aarhus both have status as national libraries, the State and University Library also being part of the infrastructure for the public libraries. As such, they are responsible for legal deposit and Netarkivet.dk that contains the Danish part of the Internet, harvested by Web crawlers. So far the Net Archive can only be used for research.

ACADEMIC AND RESEARCH LIBRARIES

Universities

Following a recent reform of Danish universities which also included the merger of some independent research institutions there are today eight Danish universities. The largest universities by far are

- Copenhagen University (est. 1479) with an academic staff of about 3500.
- Aarhus University (est. 1928) with an academic staff of about 2000.
- The Technical University of Denmark (est. 1829) is the third largest.

These three universities have stronger research profiles, than the smaller schools. The University of Southern Denmark (est. 1966), the University of Aalborg (est. 1974), the Roskilde University (est. 1972), and The Copenhagen Business School (est. 1917) are medium-sized universities while the eighth university, IT University of Copenhagen (est. 2003), is a very small university (Fig. 3).

Universities are the primary institutions for higher education in Denmark, and all of them, except IT University, have an independent research library, which the school funds and manages. In the case of Aarhus and Copenhagen universities, the libraries have an independent role, since the two national libraries also function as university libraries.

In the recent reforms of the Danish educational sector, also included the vocational educations at college/high school level. A large number of schools for engineers, nurses, teachers, and pedagogues were merged into eight university colleges. The largest of these have close to 10,000 students. The largest of these colleges have roughly the same number of students as the medium-sized universities. The students and teachers at the university

colleges were originally supported by small libraries connected to the particular education but following the mergers new and larger library organizations are being established at the different university colleges.

Special Libraries

A number of academic libraries are regulated by the Act regarding Library Services. The act specifies that the libraries participate in the general interlibrary loan cooperation and are freely accessible to the public; doing so is a prerequisite to receiving a grant for the library. The Danish Agency for Libraries and Media each year publishes a list of those libraries regulated by the Act.

There are a large number of small academic libraries. The Danish library statistic collects data from 169 academic libraries; 42 of these participate in general interlibrary loan cooperation. Of these 42 libraries, 16 are large academic libraries that provide more detailed statistics. The universities have a total of 122 departmental libraries, e.g., libraries in law and medicine.

The loan of printed materials continues to play a central role in library activities. The library.dk service and the underlying interlibrary loan cooperation are important in that regard. Downloads from subscription-based electronic journals have replaced printed materials as the most important activity for the larger research libraries. In 2006, the 16 largest libraries had 2.8 million loans of books and other printed materials and 8.2 million downloads from electronic journals. That means that two out of every three loans are now electronic.

Library roles and tasks

Academic libraries are expanding the traditional role of information provision to include new services to support activities at the parent institution. In its strategy for library development, The Danish Agency for Libraries and Media identifies five major functions of academic libraries.

The most important task is still providing information through building print collections and purchasing subscriptions to electronic journals and databases. A second activity is the creation of new interfaces to the global Web of knowledge for both students and researchers. At present, efforts are focused on integrated search, i.e., creating seamless access to the many different information resources and delivering accurate search results.

The 2003 act on universities emphasized the export and mediation of knowledge from universities. Subsequently, this has become a third major task for academic libraries. An important activity is the registration of research and the operation of current research information systems (CRIS). This role is expanding into the fourth major activity—the support for a coherent e-framework for education and research at the parent institution. There is increased focus on IT systems for supporting learning and

research. This can include systems for e-learning and handling of scientific primary data. The fifth and final task is development of information literacy skills.

Digital Library Collections and Services

Denmark's Electronic Research Library (DEFF) plays an important role in regard to the build-up of the libraries' digital collections. Among other things, it functions as a national framework for consortia buying electronic journals and databases. The DEFF-secretariat handles negotiations with vendors and administers practical aspects of the subscriptions. Denmark's Electronic Research Library supported the development of the national access system that allows all students and researchers to have remote access to electronic journals.

Denmark's Electronic Research Library provides the infrastructure for both consolidation and development of library services, and it supports the increasing consolidation of library systems and the joint development of common CRIS systems. It also support more specific projects, e.g., in information literacy. The SWIM tutorial at Aalborg University Library (<http://www.aub.aau.dk/swim2/1024/start.html>) and the library test (<http://www.librarytest.dk/>) developed by The Royal library are examples of such projects.

In addition to its own Web site <http://www.deff.dk>, DEFF has supported the development of the national science portal <http://www.videnskab.dk> and the national research database <http://www.forskningsdatabasen.dk/>.

PUBLIC LIBRARIES

The Danish public library system is regulated by the Act regarding library services, which is a framework law that obligates all municipalities to run a public library that offers both children and adults free and equal access to Danish libraries' materials. Public libraries must cooperate with school libraries. All major research and special libraries participate in the interlibrary loan cooperation free of charge.

The common database, bibliotek.dk, and a transport scheme financed by the State form the basis of extensive ILL (interlibrary loans) activity. All public libraries are to be run by professionally qualified staff. The law obliges the libraries to provide free access to all types of media, including the Internet. Public libraries together produce a number of national, Web-based services, e.g., Biblioteksvagten.dk/Ask-a-librarian, Litteratursiden.dk, SpørgOlivia (Ask Olivia).

In 2007, the Danish municipal structure was changed from 275 to 98 municipalities, which led to the merging of many public libraries. One hundred and thirty-six branches were closed that year culminating a decade of closures of almost 500 out of more than 1000 libraries. In

2007, there were 550 public libraries. The closures are seen as part of a restructuring of the libraries to accommodate the needs of the knowledge society. The remaining libraries are extending their opening hours and services, and work is going on to find alternatives to the small local branch, e.g., cooperation with school libraries, self-service branches, flexible mobile libraries, and delivery of library materials. The total budget for public libraries is 2.75 billion krone DKK (Danish crowns), which means a per capita expenditure of 502 DKK per year (2007) (Fig. 4).

There is a decrease in the loan of traditional library materials, but an increase in the use of new digital services. The average loan figure per citizen is 13 (2007). The government's strategy for the development of public libraries features three main tracks:

- Continuous development of digital services.
- Changing the physical library from storehouse to a learning, meeting, and experience space.
- Innovative thinking in terms of outreach library service.

One example of a new digital service is the loan of music files from home via the library that clears the use with the rights owners. All recorded Danish music is digitized and forms part of this agreement together with a large part of foreign music.

Outreach library service is partly Web-based and partly directed toward various target groups. Kindergarten libraries and targeted early initiatives concerning children in ghettos in the shape of bookstart programs are examples.

SCHOOL LIBRARIES

School libraries are obligatory in the Folkeskole where they have status as pedagogical service centers. Thus, they are integrated into the school and are run by teachers who have supplemented their training with a school librarian course (diploma program). The school library makes available all types of educational materials for teaching and provides books and other materials for the pupils' leisure reading. There are 1929 school libraries, and most pupils use them; 75% of pupils visit the library at least once a week. The school library forms a central part of the school's learning environment and acts as the school's innovative, mediatory, and pedagogical learning center. It supports the aims of the Folkeskole and contributes to realizing the school's fundamental values, learning targets, and action lines.

There is no statutory requirement for libraries in secondary schools. About 75% of the nearly 250 secondary schools, however, do have a library with instruction in information literacy as a central feature. Upper-secondary school libraries support the pupils' learning environment

Fig. 4 Interior of children's library at Hjoerring Public Library.
Source: Photo Fjord and Bosch by Laura Stamer.

and study competence, and studies show that traditional library service is heading toward a new form of learning and knowledge center. Focus is directed at interdisciplinarity, and many places are working intensively on introducing a new project culture. In 2007, the upper secondary schools were changed from being county institutions to private institutions. Beginning in 2009, these schools will be included in Denmark's Electronic Research Library.

School libraries are supported by 16 government centers for educational services. These centers offer information on and loan of educational materials, pedagogical advice, and guidance to teachers, assistance with the production of educational materials, and educational programs, such as instruction in IT application.

Library and Information Science Education

The Royal School of Library and Information Science (<http://www.db.dk/english>) was established in Copenhagen in 1956 as a professional school with 4-year educational programs. In 1973, a branch was established in Aalborg in Jutland. Until the late 1960s, research and academic libraries offered a program for library assistant, which then became a 4-year education program at research and academic libraries. In the mid-1980s, the two programs merged into one.

In 1999, the school became an institution of higher education with bachelor's, master's, and Ph.D. programs (3 + 2 + 3) and a diploma program which consists of a 1-year advanced level program following a bachelor's degree. The school also offers a number of diploma and

master's programs. Prior to the school's change to university status, an assessment was carried out according to American Library Association Standards for accreditation of Master's Programmes in Library and Information Studies with a very gratifying result.

A research evaluation, carried out by five recognized international and national researchers in 1999 concluded that the school's research was at the highest level. The school employs about 100 researchers with a broad spectrum of research fields. It has made its mark internationally through research within information retrieval, domain analysis, and knowledge organization. Several Danish universities have conducted information scientific research projects and established educational programs bordering on information science.

The educational programs at the Royal School of Library and Information Science are directed at tasks in both public and research libraries, public administration, organization, and private businesses. Students trained at the school are increasingly being employed in all types of knowledge-based institutions. Both the classical library services and the rapidly growing digital services play an ever-increasing role: organization, mediation, and sharing of knowledge are of fundamental importance to society's economic and cultural development and cohesion. About half of the school's graduates are employed outside the library sector. The school has close to 1000 students, about 200 in Aalborg, and 800 in Copenhagen.

The Royal School of Library and Information Science has a Department of Continuing Education and Consultancy, which is responsible for continuing education and

deals with advice and development tasks. The Department of Continuing Education and Consultancy is visited annually by about 5000 course participants and arranges about 300 courses a year.

Associations

The association, “Danmarks Folkebiblioteksforening,” was founded in 1905 and was merged with the Danish Library Association in 1920. The aim of the association was to further the library cause in Denmark, and for more than 50 years it represented all library interests in the country. Today, the association membership includes local authorities responsible for cultural affairs and institutions as well as personal members, primarily among library staff. It lobbies for the continuous development of public libraries and publishes the journal *Danmarks Biblioteker* (<http://www.dbf.dk/Default.aspx?ID=4126>).

In 1969, library employees broke away from the association and formed The Danish Union of Librarians, which represents the interests of professionally trained librarians. Today, the union has 5500 members and publishes the journal *Bibliotekspressen* (<http://www.bf.dk/Service/English.aspx>).

Research libraries broke away in 1978 and formed the Danish Association of Research Librarians, a professional organization for research libraries and their employees (<http://www.dfd.dk/uk.php>).

The Municipal School Library Association dates from 1919 and organizes municipalities and their politicians with particular interest in school libraries, <http://www.ksbf.dk/page/foreningen.html> while school librarians have their own association, the Association of School Librarians (<http://www.emu.dk/gsk/skolebib/>).

Danish public library directors are organized into the Association of Library Directors, <http://www.bibliotekslederforeningen.dk/>, while the libraries’ clerical staff and library assistants are organized in HKstate (http://www.hk.dk/stat/landssammenslutninger/statslige_biblioteker_og_arkiver) and HK Municipal Library Committee (<http://www.hkkommunal.dk/sw30576.asp>). These associations’ homepages are only available in Danish.

Since 1989, all of the Danish associations have collaborated in the Library Umbrella, just as most of them are members of the European library associations, EBLIDA (European Bureau of Library, Information and Documentation Associations), and IFLA (International Federation of Library Associations).

ARCHIVES AND ARCHIVAL SCIENCE

Legislation

The Danish Archives Act regulates preservation and disposal of public records, the public archives’ activities, and

the public’s access to records. It states that public archives must:

- Ensure the preservation of records of historical value or that serve as documentation of conditions of important administrative or legal importance to citizens or authorities.
- Guarantee the possibility of disposing of non-preservation-worthy public records in cooperation with those authorities affected by the law.
- Make records available to citizens and authorities, including for research purposes.
- Instruct citizens and authorities in the use of records.
- Do research and spread the knowledge about research results.

The Danish Archives Act is administered by the State Archives, a government agency under the Ministry of Culture that determines the detailed rules for preservation and disposal of public records. Municipalities and regions may choose to establish their own archives for the preservation of their records. The State Archives are obliged to cooperate with these regional or local archives. Government authorities must transfer their records before they are 30 years old. Special rules apply to digital records.

The Archives Act defines the rules for accessibility to public records. Public records are normally freely available when they are 20 years old. Records that contain information about an individual’s private, personal, or financial, situation are only available after 75 years. There are a number of regulations about accessibility to specific types of records. In special cases, authorities transferring records can, in cooperation with the State Archives, determine accessibility deadlines for specific archive groups. The Act states that it is possible to seek access to records that are not immediately accessible. In such cases, the State Archives, possibly in collaboration with the relevant public authorities, decide whether special permission may be granted. The State Archives can collect and make available private records from individuals, associations, organizations, and companies. In such cases, agreements must be made on accessibility between the transferring party and the State Archives.

National, Regional, and Local Archives

“The State Archives,” consists of the Danish National Archives, the Regional Archives of Zealand, Regional Archives of Funen, Regional Archives of Southern Jutland, Regional Archives of Northern Jutland, the Danish Data Archives, and Danish Business Archives. The State Archives altogether employ about 300 people.

The Danish National Archive in Copenhagen is the central administration’s archive and collects and stores records from all Danish central authorities—ministries,

government agencies, and the armed forces—and from private individuals and organizations. The National Archive contains about 168,000 shelf meters of records that are made available to the public in the reading rooms of the State Archives. The reading rooms have about 17,000 visitors each year, principally genealogists, researchers, and students.

The public archives in Denmark are quite professionalized, partly because they are administered under the authority of the State Archives. The State Archives' dual function as an agency for the administration of the Archives Act and as a cultural institution for the preservation, accessibility, and mediation of records has proved to be effective. As opposed to many other national archives, the State Archives no longer have a backlog. With the prospect of new, climate-regulated stacks that can accommodate the entire collection a volume of almost 400,000 shelf meters, the State Archives find themselves in an extremely favorable situation.

Denmark also has a number of "Regional Archives" that collect and store records from public regional authorities, primarily regions, and municipalities. These include:

- The Regional Archives of Zealand, Lolland-Falster, and Bornholm are also situated in Copenhagen.
- The Regional Archives of Zealand contain about 69,000 shelf meters of records and are visited by about 18,000 people each year in their reading rooms.
- The Regional Archives of Funen in Odense collect and store records from public regional authorities, primarily regions, and municipalities.
- The Regional Archives of Funen contain about 20,000 shelf meters of records and annually welcome about 9000 visitors to their reading rooms.
- The Regional Archives of Southern Jutland in Aabenraa collect and store records from public regional authorities, primarily regions, and municipalities.
- The Regional Archives of Southern Jutland contain about 18,000 shelf meters of records and have about 4000 visitors each year in their reading rooms.
- The Regional Archives of Northern Jutland in Viborg collect and store records from public regional authorities, primarily regions, and municipalities.
- The Regional Archives of Northern Jutland contain about 62,000 shelf meters of records and about 11,500 visit the reading rooms each year. Here you also find the State Archives' Filming Centre, which does microfilming and digitization of the records kept in the State Archives.

The Danish National Business Archives is a research institution that collects and preserves important historical source material about the development of Danish business life and makes it available to the public. The Business Archives also act as archive for Aarhus municipality. They contain about 50,000 shelf meters of records and

about 3500 visitors find their way each year to the reading rooms.

Danish Data Archives in Odense collect, preserve, and deliver digital research data from social science, medical science, and history. Quantitative research data in the form of questionnaires make up most of the collection. Danish Data Archives' material is available via search catalog on their homepage. The State Archives' collections are searchable via the database DAISY, which is available online. Digital historical data in the shape of archiving versions are available via the database SOFIA.

Separate from the State Archives are a number of municipal archives. Among the largest are Copenhagen City Archives, Aalborg Municipal Archives, Vejle Town-historical and Municipal Archives, and Frederiksberg Municipal Archives. State archives typically offer search in special databases. Finally, there is DANPA, Denmark's National Private Archive Database where one can search registrations of private archives from most large archives in Denmark.

College and University Archives

The archives of Danish institutions of higher education are to be found in the State Archives. The archives of Copenhagen University, Technical University of Denmark, and the Aarhus University School of Education are placed in the Danish National Archive. The archives of Aarhus University and Aalborg University are placed in the Regional Archives of Northern Jutland, those of the University of Southern Denmark in the Regional Archives of Funen and Roskilde University archives in the Regional Archives of Zealand.

The State Media Collection, part of the State and University Library, collects, preserves, and mediates Danish TV and radio broadcasts, commercials and sound recordings from parliamentary debates, news bulletin manuscripts and Danish video releases. Researchers (including journalists) and students/lecturers at institutions of higher education can borrow the TV and radio broadcasts. Everyone can use the audiovisual collections in the library, even the legal deposit material, since they cannot be loaned to other libraries or to private individuals.

According to the Film Act, the Danish Film Institute is obliged to ensure the preservation of films and documentation material about films, to collect film and TV literature, to do research and to make the collections available to the public. The archives of the Film Institute hold more than 30,000 titles and contain all kinds of films shown in Danish cinemas from the beginning of the history of film in 1896 to the most recent films that are legally deposited with the archives. The film archives work actively for preventative preservation, conservation, and digital preservation/conversion. The Institute's films are available online in the database "Danmarks Nationalfilmografi."

DR Archives and Research is part of Denmark's Radio and contain archives and library. Apart from servicing the employees at DR, it sells archival and research services to external stakeholders. DR Archives and Research does not lend from its archival collections with TV broadcasts, but it is possible via the country's libraries—for research purposes—to use TV materials.

DRs Radio Archives file and maintain the broadcasts that must be preserved for posterity. The radio broadcasts go back to the 1930s and cover recent Danish history politically, socially, and in societal terms. Add to this radio dramas, montages, and recitals. There is no public access to the collections of radio broadcasts, but it is possible to buy individual broadcasts. Radio materials from the State Media Collection can be used for research purposes.

Other Archives and Repositories

The Labor Movement's Library and Archives in Copenhagen contain a large collection of archival material concerning the history of the labor movement in Denmark. The Danish Emigration Archives in Aalborg are The National Collection of records on the history of emigration in Denmark. The Map and Land Registry Agency contains previously valid cadastral maps, cadastral protocols, and registered cadastral cases, including surveying information. The collections cover the period from 1844 to the present. For information on Greenland and the Faroe Islands, see National Museum of Greenland and Archives and the Faroese National Archives.

Digital Archival Collections and Finding Aids

Cf. the Archives Act, the State Archives collect, store, and make available Danish authorities' digital records. Development of search tools for the digital collections is undergoing a tremendous process of change. The database SOFIA, which contains the authorities' digital archival version, as of 2008 was only available in the reading rooms of the State Archives. An online solution is expected to be implemented soon.

Archival Science as a Discipline and Profession

Archivistics, as profession and discipline, has emerged in Denmark mainly under the auspices of the State Archives and to a lesser extent the municipal archives. The State Archives employ about 200 archivists, providing a professional archive environment. Extensive Nordic collaboration is going on with expert seminars, Nordic Archives Academy, exchange of staff and the Nordic Archive Days. The central publication relating to archives and archivistics in the North is *Nordisk Arkivnyt*, published four times a year.

Education for archivists and records managers

Denmark has no actual archivist training course. However, Aalborg University, together with Aalborg Municipal Archives, has established a training program in information administration that includes courses such as archive theory, databases and communication, and a final project. The program, first offered in 2008, runs for two semesters. A student enrolled both terms can earn 60 points European Credit Transfer and Accumulation System. In addition, the State Archives offer a number of internal courses for their archive professional staff.

Professional associations

There are four major associations related to archives and archivistics.

1. *The Organization Danish Archives (ODA)* works to increase public awareness of the importance of Danish Archives and also attempts to promote collaboration, coordination and other kinds of activities that can enhance Denmark's archival cultural heritage.
2. *Forum for Knowledge, Information, Documentation, and Archives (VIDA)* is an association whose aim is to encourage rational archival organization, particularly in the corporate sector. Here companies, organizations, and individuals are gathered together, who have journalizing, electronic document management as areas of responsibility, occupation, or interest.
3. *The Archives Association* arranges functions open to anyone interested in archive professional issues, or who just has a general historical interest. There are 6–8 functions a year.
4. *The Association of Local Archives (SLA in Danish)* brings together people with archival interests in Denmark in a common endeavor to heighten the quality in the work with preservation of the cultural heritage. The association has more than 400 members, distributed on 13 districts that each covers one of the former counties. Members of the association profit from each other's experiences and expertise and from the development work carried out by SLA's committee.

Electronic Records as Archival Documents

The Archives Acts does not differentiate between electronic/digital records and paper records. The State Archives thus have the obligation of collecting, storing, and making available all records whatever the medium and format. The State Archives have collected electronic/digital records since the early 1970s.

In order to preserve and make available electronic/digital records, the State Archives conducted a large conversion project during the past few years where electronic/

digital records of older formats are recorded on DVD in a searchable format. The project ended in 2008, and from now on focus will be placed on accessibility of the collection of electronic/digital records.

Preservation

The State Archives do not perform actual conservation of its collections. For the purpose of conservation, a professional consultant is employed who monitors the collections and decides which records should be conserved. The conservation process is outsourced to The Royal Library's Preservation Department.

The State Archives are in the process of introducing climate control regulations for all new stacks, to ensure that a stable, low temperature and stable, low, relative humidity will inhibit the deterioration paper records. In addition, the State Archives stores the majority of its collection in acid-free, bar-coded boxes.

Conservation and preservation of digital records take place as mentioned above in a special format and structure conversion project.

MUSEUMS AND MUSEOLOGY

Introduction—The Danish Museum Sector

The Danish museum sector covers a broad and varied spectrum of institutions and subjects. The major institutions share the same legal framework—The Danish Museum Act—and receive funding or subsidies from the Ministry of Culture. Almost 100 museums cover cultural history, another 35 focus on art, and three specialize in natural history (geology, zoology, and botany).

The number of visitors at Danish museums has been stable for the past 10 years, totaling approximately 10 million visitors a year. In 2006, the state-owned and state-subsidized museums introduced free access for people under age 18. At the National museum and “Statens Museum for Kunst—The Danish National Gallery,” free access is also given to adults. Since 2006, there has been a 2% yearly increase in the number of visitors. In 2007, the total number was 10.8 million. That is the equivalent of two museum visits a year per inhabitant in Denmark.

Total public spending on the museum sector is approximately DKK 1.1260 million a year, of which the State's share is DKK 716 million (2006). There are eight state-owned museums that are fully funded by the central government, and 123 others that are approved by the State and receive partial funding.

The state-subsidized museums are owned by local authorities, by independent institutions or by an association whose objective is to run the museum. These three forms of ownership are equally prevalent. The central government's share of funding for state-subsidized

museums is approximately 35% of their total expenses. There are 19 state-subsidized museums that receive extra State funding, because they have special research and/or dissemination activities. Some of these museums also handle tasks at the national level.

Legal Framework

The state-owned and state-recognized museums are regulated by the Museum Act, passed in 2001.

According to the law, the general purpose of the museums is to safeguard Denmark's cultural and natural heritage and secure access to and knowledge about this heritage and its interaction with the world around us. The purpose is realized through the five key function that constitute the tasks of the museum: collecting, registering, preserving, researching, and disseminating information. The act identified three types of museums: 1) natural history museums; 2) art museums; and 3) cultural history museums. The 2006 revision of the act introduced free access for children and made some changes related to the reform of the Danish municipalities.

Heritage Agency of Denmark

This agency promotes collaboration between museums and supports the development of individual museums. It makes recommendations to the Minister of Culture about which museums are to be recognized by the State and thus eligible for state subsidies. It also administers state subsidies for these museums. Other tasks include listing buildings of national significance and the protection of ancient sites and monuments, and of the archaeological excavations undertaken by Danish museums. The Heritage Agency also administers various funds for which both state-owned and state-subsidized museums can apply annually. Such state grants provide support for research projects, study trips, purchases, publication of books.

In addition to the Heritage Agency, certain museums have special roles in regard to other museums. The National Museum of Denmark, “Statens Museum for Kunst—the Danish National Gallery” and the Danish Museum of Natural History are the principal museums for cultural history, history of art, and natural history, respectively. These three museums have a special status and offer expert advice to other museums in Denmark.

Museums of Art

There are three state-owned art museums. The Danish national “Statens Museum for Kunst—the Danish National Gallery,” is according to the museum law, given has the responsibility of illustrating Danish and foreign visual arts, primarily from the western world after 1300 A. D. The museum's collections constitute almost 9000 paintings and sculptures, more than 240,000 works of art on

paper as well as more than 2600 plaster casts of figures from ancient times, the Middle Ages, and the Renaissance. The major part of the museum's older collections comes from the art collections of Danish kings.

The two other State art museums are the Ordrupgaard Collection and the Hirschsprungske Collection. The former is named after the village of Ordrupgaard, which lies just outside Copenhagen. Its collection features nineteenth-century French and Danish art, including works by important Romantic, Realist, and Impressionist painters. The Hirschsprungske Collection owes its name to Pauline and Heinrich Hirschsprung, who donated their comprehensive collection of nineteenth-century Danish art to the Danish State in 1902.

Among the 35 art museums are the ARoS (formerly Aarhus Art museum), which was established in 1859 and opened in a new building in 2004. It offers Denmark's largest art collection outside Copenhagen and has notable collections of Danish art that span 300 years as well as exhibitions of contemporary international art. The Ny Carlsberg Glyptotek in Copenhagen is one of Denmark's most popular museums. It houses more than 10,000 works divided into two principal collections. One is devoted to the Mediterranean cradle of Western culture and the other to Danish and French art from the nineteenth and twentieth centuries.

Outside Copenhagen are two museums of twentieth-century art. The Arken Museum of Modern Art, which was opened in 1996, collects Danish, Nordic, and international art with special emphasis on work from 1990 to the present. The Louisiana Museum of Modern Art offers a collection of more than 3000 works, produced primarily after 1945, that concentrates on more compact groups of works and artists.

Cultural History Museums

The Museum Act states: "The cultural history museums illustrate change, variation, and continuity in the living conditions of human beings from prehistoric times to the present." The National Museum of Denmark is the country's principal cultural history museum. Its responsibility is to illustrate Denmark's culture and the interdependence of all the world's cultures.

In addition to exhibitions of Denmark from prehistory through the Middle Ages and the Renaissance to modern times, the museum houses exhibitions from the ancient cultures of Greece, Italy, the Near East, and Egypt. It is also in charge of some of the archaeological investigations that the Museum Act specifies as important in securing the cultural and natural heritage.

Denmark has three additional cultural history museums. The Danish Defence Museum has two exhibitions: The Royal Danish Arsenal Museum, which exhibits the development of small arms and edged weapons during the last 500 years, and the Royal Danish Naval Museum,

which presents naval models and marine paintings. The Defence Museum also exhibits historic warships, which include the frigate, Peder Skram, the last Danish submarine, Sælen, and the fast attack boat, Sehested.

The Danish Agriculture Museum illustrates farming and the life of farming families from the Late Stone Age through the agricultural reforms that took place from the late eighteenth century to the present day. The collection contains approximately 70,000 items, some of which are extremely large. The museum's buildings extend over approximately 24,000 m², including 8000 m² of exhibition space.

The Danish Museum of Hunting and Forestry is one of the largest of its kind in Europe. With 3000 m² of exhibition space, the museum presents the history of hunting and forestry in Denmark from the Stone Age to the present day.

Danish history from the Stone Age and Iron Age can be experienced at several other places. The Prehistoric Museum, Moesgaard, near Aarhus in Jutland, offers a wealth of relics from prehistoric Denmark to the Viking Age, including a large collection of runic stones. On the border between museums and experience centers, Hjemsted Oltidspark in southern Jutland and Lejre Experimental Centre near Roskilde, are worth mentioning.

Natural History Museums

The natural history museums illustrate nature, its development, contemporary environment, and the way it's related to human beings. In 2004, four institutions were merged to create The Natural History Museum, which is responsible for maintaining and building up natural history collections, for carrying out research in the natural sciences, and for presenting the current state of knowledge about natural history to the general public. The four merged institutions, the Botanic Garden, the Botanical Museum and Library, the Geological Museum, and the Zoological Museum, are now a department of the University of Copenhagen. The museum's exhibitions play an important role in teaching and public outreach.

The Ministry of Culture grants subsidies to four natural history museums. The Natural History Museum in Aarhus, the second largest of its kind in Denmark in both size and exhibition area, contains more than 5000 different species of animals from all over the world. Svendborg Zoological Museum (naturama) focuses on mammals and birds whereas the Mid-South Jutland Museum exhibits primarily fossils collected in the Gram Clay Pits (Gram Lergrav), which have fossils as much as 8 million years old. The Fur Museum contains a unique collection of 54 million-year-old fossils.

Digital Museum Exhibits and Services

The Heritage Agency coordinates registration of the museum's collections. The cataloging system Regin was

made available to the museums in 2003, and the data are presented on the Internet at <http://www.kulturarv.dk/mussam>. With this service, it is possible to get an overview and search the collections of the cultural heritage museums.

A similar service is available for the arts museums. The central register of works of art in Danish museums and collections was founded in 1985 and went online in 1996. The register holds information on approximately 39,000 works by Danish and international artists. It is available at: <http://www.kulturarv.dk/kid/Forside.do>. In addition, there is the possibility of searching for museums and institutions by geography, subject, or collection at: <http://www.dmol.dk/engelsk/start.asp>.

A 2006 ministerial report recommended an increased focus on digital mediation and increased cooperation and knowledge sharing, and it proposed a specific focus on mediation for children in a digital environment. It also highlighted some of the many services and projects developed by the museums themselves. A good example is <http://www.kongedragter.dk/> where it is possible to study the clothing of Danish monarchs. At Zoom Ordrupgaard (<http://www.zoomo.dk>) the public can experience close ups of pictures, compare pictures, and get tips on analyzing them. Another example of digital mediation is <http://www.absalon.nu>, which is a collaboration between the local library, archive, and museum presenting the history of Copenhagen on the Web. At <http://www.tilbygningen.dk> (the annex), audiences can experience a virtual addition to Thorvaldsens Museum and take a trip around the collections. The museums are continuously developing new digital exhibitions and services, frequently with funding from the Kulturnet Danmark funding pool. One such example is <http://www.vildmedwillumsen.dk>.

Another kind of service presented by Danish institutions in arts, design, and architecture is a joint portal <http://www.arkade.dk>, which offers a collection of links, the possibility of cross-searching the institution's catalogs and access to other digital information resources.

Two initiatives seem to hold interesting prospects for future mediation. One is <http://www.emuseum.dk> where the museum's collections and mediation is directly linked to teaching. The other is <http://www.danskkulturarv.dk> which is a pilot project that attempts to show how digitization and, in particular, mediation can be cross-institutional and bridge the traditional division between archives, libraries, museums, and other institutions, such as the Danish Broadcasting Cooperation.

Museology as a Discipline and Profession

The universities have a long history of offering education in museology as subjects in arts history and ethnography, but there was no coherent education specifically focused on museology until 1977 when it was established as an interdisciplinary, optional course at the Department of Art

History at Aarhus University. In 2001, museology was offered as a supplementary program at the University of Aarhus, and in 2002, museology was integrated in the B.A. program at the University of Copenhagen. In 2005, a master in museology was established at the University of Aarhus. The latter program is divided into four modules: international museum theories and methods, organizational museum theories and methods, museum communication, and finally a master's project. Additional teaching study in museology is offered at the University of Roskilde and at The Royal School of Library and Information Science.

Training for curatorship and museum administration

For a number of years, The Museumshøjskolen (a folk high school) was an important center for the development of museology in Denmark. The school offered further education to employees at Danish museums. In 2006, the Museumshøjskolen was merged with the Association of Danish Museums, which offers a number of shorter courses as well as further education. For example, the training in museum administration and management is offered at the diploma level.

The School of Conservation, part of The Royal Danish Academy of Fine Arts, was established in 1973. The education as conservator is a 3 year bachelor degree followed by 2 years of graduate studies. After 5 years of study, the student earns the degree Cand.Scient.Cons. The school also offers a 3 year research program (Ph.D.).

Professional associations for curators and museum administrators

The Association of Danish Museums, which covers almost all Danish museums, organizes a number of different subject-based informal networks. One of these is a museology researcher's network, which has evolved into a more permanent organization with regular meetings.

Key contemporary issues—preservation, access, educational role

The growing importance of museology as a profession, the Museum Act of 2001 and the establishment of the National Heritage Agency all signal a new and more visible profile for Danish museums. The Danish reform of municipalities and counties has entailed new funding structures, and some mergers in the museum sector. These issues have dominated the debate for the past few years.

These developments have also served as a catalyst for a debate on the concept and functions of the museum. There is a growing emphasis on the educational and interpretive role of the museum in relation to the other four functions (collecting, registering, preserving, researching). Mediation is seen as increasingly important as the museums try

to contribute to other societal goals, such as education, tourism, social inclusion, and economic development. This has sparked a debate on whether museums risk becoming mere entertainment, like the Tivoli amusements, or whether, according to new theories of learning, entertainment, and education can be combined in innovative ways. At the same time, digital development challenges the traditional concept of museums as dependent on collections and highlights the possibilities of cross-institutional cooperation.

CONCLUSION

Danish libraries, museums, and archives are highly advanced and are undergoing rapid transformation as a result of the knowledge society's new standards for hybrid institutions. Although the library, archives, and museum sectors are formally separated and each has its central state agency, the fundamental objectives, and conditions for the institutions are similar.

All knowledge and culture institutions are facing a radical digital challenge that has to do with the materials and services of the institutions, their service to the users, their organization, and expertise.

For a number of years, work has been going on locally as well as centrally concerning cooperative digital projects between the three types of institution. Nationally, work has centered around an adaptation of search systems to make it possible to search in all collections at the same time. Locally, focus has been on the work with joint Web presentations with local history subjects or themes of common interest.

The Danish Ministry of Culture is preparing a national strategy for digitization of cultural heritage materials. The existing interim report reveals the desire for interdisciplinary presentation of digital cultural heritage based on user needs. It also points out that consolidated solutions for preservation and mediation will reduce costs in connection with digitization and stresses the need for a consolidated data warehouse. Finally, functional division of labor with a few centers of expertise is contemplated.

Confronted by new challenges libraries, archives, and museums are all moving toward a realignment of their

institutional culture, going from a collection orientation to a user-centered orientation. The need for this can be most clearly observed in work with children and young adults. Particularly in libraries and museums, there have been increased efforts to establish new modes for communication and interaction based on Web 2.0, inclusion, and active participation. The importance of keeping the interest of children and young as users of cultural institutions is underscored by an increasing political understanding of the importance of culture- and knowledge-institutions in increasing social cohesion and stimulating collective innovation.

Descriptive Cataloging Principles

Elena Escolano Rodríguez

National Library of Spain, Madrid, Spain

Abstract

This entry explains the international standard that guides bibliographic description, the International Standard Bibliographic Description (ISBD) that contains the principles of descriptive cataloging. The standard will be analyzed by giving its definition, purposes, principles, and objectives; and by explaining its structure, uses, and acceptance around the world. Its need will be justified by providing a short history of the background and evolution of the publication, ending with the current version of the consolidated ISBD that integrates the description of all types of resources that had been covered by specialized ISBDs.

INTRODUCTION

Bibliographic description is done in order to identify and retrieve resources. The descriptive part of a bibliographic record represents a substitution for the resource, a kind of surrogate. It helps general users identify and select resources, but it is especially useful for librarians, because it allows them to perform many collection development tasks without needing to recall volumes from the stacks. In addition, it is useful for library inventory. Bibliographic descriptions also can be adapted to meet the needs of specific types of users.

To standardize means to bring conformity with “something established by authority, custom or general consent.”^[1] The International Standard Bibliographic Description (ISBD) is the international standard approved by IFLA for bibliographic description.

The International Standard Bibliographic Description (ISBD) was recommended by the ISBD Review Group, and approved by the Standing Committee of the IFLA Cataloguing Section. Preliminary consolidated ed.; München: Saur, 2007. This work is cited as “ISBD, 2007” hereafter in this text. Per the IFLA Web page (<http://www.ifla.org/III/index.htm>, accessed November 2007): “The International Federation of Library Associations and Institutions (IFLA) is the leading international body representing the interests of library and information services and their users.”

The ISBD is the standard that determines the data elements to be recorded or transcribed in a specific sequence as the basis of the description of the resource being cataloged. In addition, it employs prescribed punctuation as a means of recognizing and displaying these data elements and making them understandable independently of the language of the description.

PURPOSE

The ISBD *aims* to

- “make records from different sources interchangeable, so that records produced in one country can be easily accepted in library catalogs or other bibliographic lists in any other country” (*ISBD*, 2007; 0-1). It has furthered cooperative activities and projects such as interlibrary loan, shared catalogs, and networks at national and international levels. Given the huge number of cooperative projects, a high level of standardization is needed to be effective.
- “assist in the interpretation of records across language barriers, so that records produced for users of one language can be interpreted by users of other languages” (*ISBD*, 2007; 0-1). This supposes a *lingua franca* among librarians.
- “assist in the conversion of bibliographic records to electronic form;
- “enhance interoperability with other content standards” (*ISBD*, 2007; 0-1).

It is important to highlight that the ISBD is addressed to national bibliographic agencies that have the responsibility to contribute to Universal Bibliographic Control (UBC). UBC is the IFLA’s program for promotion of a world-wide system for the control and exchange for bibliographic information. “National bibliographic agencies are called on to accept responsibility of creating the definitive record for each resource issued in that country. It is therefore recommended that descriptions prepared by them contain all the mandatory elements set out in the ISBD insofar as the information is applicable to the resource being described” (*ISBD*, 2007; 0-2); that is why

the ISBD establishes if the element is mandatory, optional, or conditional, to accomplish the objective that the description aims to identify the resource. Although intended for national bibliographic agencies, the ISBD application is also recommended for libraries that share bibliographic data with others because normalization improves cooperation.

Originally the development of the ISBDs was pushed by the automation of bibliographic control as well as the economic necessity of sharing cataloging. Nevertheless, the ISBD is independent of any specific electronic format for information. It is useful and applicable for bibliographic descriptions of all kinds of bibliographic resources in any kind of catalog, whether Online Public Access Catalogs or catalogs less technologically advanced.^[2]

The intention and objective of the International Federation of Library Associations and Institutions (IFLA) have always been to support the continuing development of library activities, and at the same time to help all countries to incorporate such developments. "IFLA is the global voice of the library and information profession . . . help libraries and information services to fulfil their purposes and to shape responses to the needs of clients in a rapidly changing global environment." (In IFLA Web site: <http://www.ifla.org/III/index.htm> (accessed October 2007)). Therefore, a standard from IFLA such as the ISBD must take into account all library situations.

The previous statement, in conjunction with the need for the standard, cannot be better explained than with the director of the IFLA International Office for UBC, Dorothy Anderson's words in 1974, which in spite of the passage of time are still current:

In a world which is unevenly composed of over-privileged and under-privileged countries, where economic resources rest unequally and what in one country seems commonplace—computers, typewriters, copying machines—in another may seem a far distant and impossible dream, yet the objective of international standards rests firm with or without computer. All countries can participate as the component parts of a world wide UBC system if their contribution follows patterns and standards that are universal; and equally can receive.^[3]

Today all kinds of resources coexist with direct access resources: books, printed serials, etc. sharing space with remote-access resources. Description, as made traditionally, provides basic and brief information of resources to enable identification of the document, to select or disregard it, and to give access to electronic resources through links.

That is why the ISBD is the agreed-upon standard, on which the descriptive portion of the bibliographic record should be based. This consensus is reflected in the Statement of International Cataloging Principles that is being developed through a series of regional IFLA Meetings of Experts on an International Cataloging Code (IME ICC) (http://www.d-nb.de/standardisierung/pdf/imeicc-statement_principles-2008.pdf).

The ISBDs have guided the work of national cataloging committees in updating their codes to promote internationally accepted practices. This is a point underscored by the compilations of practices by various rules that were prepared for these IFLA Meetings of Experts on an International Cataloging Code. (IME ICC Web page, available at http://www.d-nb.de/standardisierung/afs/imeicc_index.htm (accessed October 2007). http://www.d-nb.de/news/pdf/code_comp_2003_europe_2.pdf (accessed October 2007) and http://www.loc.gov/loc/ifla/imeicc/source/code-comparisons_final-summary.pdf (accessed October 2007)). From these overviews, the general impression is overall compliance and considerable harmony among the national codes and with IFLA's recommended stipulations in the ISBDs. From the regional meetings we know

- Europe has the greatest number of cataloging codes in use, and one of them is AACR2.^[4]

Regarding the ISBD, it was acknowledged as a great achievement of international standardization for descriptive cataloging that requires the transcription of identifying information from the item at hand to create the standardized areas of description and ISBD goes on to state the basic elements to include in such descriptions, the order of those elements, and the prescribed punctuation, so the resulting records are understandable worldwide, regardless of language or script.

For IME ICC1, rule makers in Europe were asked to compare their codes and 18 reports on their cataloging codes were received. In their overviews were two questions related to ISBD acceptance and the general outcome was that all codes were based on ISBD.

Results of rule comparisons on ISBD from First IFLA Meeting of Experts on an International Cataloging Code, Frankfurt, Germany, July 28–30, 2003. (Web site, available at http://www.d-nb.de/standardisierung/pdf/code_comp_2003_europe_2.pdf (accessed October 2007)). From the 18 responses 15 were affirmative, and from the three left it can be deduced also to be based on ISBD, although the libraries did not answer in the same way, resulting in a wrong interpretation on the comparison. This can be deduced by the second answer to 2.2: KBRSM (Lithuania), did not answer to the question 2.1, but in the answer to the 2.2 (http://www.d-nb.de/standardisierung/pdf/code_lithuania.pdf) it was confirmed "Our rules of description are based fully on ISBD. No different rules are applied." Also KSB (Sweden) recognizes, in the same document page 1 when citing their code (http://www.d-nb.de/standardisierung/pdf/code_comp_2003_europe_2.pdf) that the code is translation of AACR2, which is the first one in recognizing it. And finally the last code not cited in the question 2.1, is the RAK (Germany) in which question 2.2 (http://www.d-nb.de/standardisierung/pdf/code_rak.pdf) says: "The cataloging code RAK is principally based on ISBD

for rules for description. RAK-WB was based on ISBD (M) edition 1974. For the special codes of RAK, other ISBDs were partly, but not thoroughly used.”

- The IME ICC for South America was structured a little differently from the European meeting. Unlike Europe, where there are several rule-making bodies and different cataloging rules, Latin American and Caribbean countries typically follow the *Anglo-American Cataloguing Rules* or the Spanish rules, *Reglas de catalogación*. These codes were already compared in IME ICC1 and their basis on ISBD was confirmed.^[5]
- “The Middle East has no rule making bodies and the countries typically follow the *Anglo-American Cataloguing Rules*.”^[6]
- From IME ICC for Asia reports, it is known that “China, Japan, and Korea have a history of rule making bodies . . . Many other countries in Asia follow the *Anglo-American Cataloguing Rules* or have a local set of rules based on AACR2.”^[7] So they recognized their rules are based on and consistent with ISBD.
- From IME ICC for Africa, of 29 countries, there were 19 responses. Twelve responded that they apply the ISBD directly while the rest apply codes already revised which were based on ISBD, such as AACR2 and AFNOR rules.
- International Standards used in Sub-Sahara Africa. In *Fifth IFLA Meeting of Experts on an International Cataloguing Code*, Pretoria, Durban, South Africa, August 14–15, 2007. Available at http://www.imeicc5.com/download/InternStand_Sub-SaharaAfrica.doc (accessed October 2007).

The IME ICCs have been very useful for the ISBD revision work, as there have been many suggestions to be considered in the future. Suggestions have come from the recognition of the different languages and scripts and also “cultural” patterns of publications that will be taken into account in the continued revision, and that will help to improve the ISBD and its interpretation.

OBJECTIVES AND PRINCIPLES

In order to know and understand this document language that is the ISBD, it is necessary to keep in mind the underlying objectives and principles.

The objectives are to assist in finding, identifying, selecting, and acquiring a resource, and to assist in navigating among resources. But to explain more in-depth the actual consolidated ISBD, it is necessary to address the objectives that guided its development (*ISBD*, 2007; vii–viii):

- “To prepare a consolidated, updated ISBD from the specialized ISBDs in order to meet the needs of catalogers and other users of bibliographic information.”—

here has been added cataloger’s convenience to stress that not only the final user is concerned, but also that catalogers represent a large part of users with special needs to carry out their tasks, and this must be taken into account.

- “To provide consistent stipulations for the description of all types of resources to the extent that uniformity is possible, and specific stipulations for specific types of resources as required to describe those resources.” This objective represents the practical application of what has been called the Principle of integration by which the description of all types or resources must be based in one set of rules in a uniform manner.

Uniformity in describing bibliographic entities, irrespective of the medium in which they are embodied, is desirable for several reasons: it serves the objectives of the catalog, particularly the collocating objective; it serves user convenience in providing a common interface to bibliographic information; and it serves the principle of parsimony in achieving economy of expression. . . . Early in the 1970s reaction set in, and a swing began away from specialization and toward integration.^[8]

The principles are

- “The primary purpose of the ISBD is to provide the stipulations for compatible descriptive cataloging worldwide in order to aid the international exchange of bibliographic records throughout the international library and information community (e.g., including producers and publishers).” This is the principle of standardization. It supposes the most important achievement of the twentieth century, the IFLA *lingua franca* between libraries that is ISBD, necessary for communication and cooperative projects. The specific “goal of reducing bibliographic effort so that one item need be described only once worldwide necessarily assumes adherence to a uniform level of description . . .”^[9]
- “Different levels of cataloging will be accommodated, including those needed by national bibliographic agencies, national bibliographies, universities, and other research collections.” Although intended largely for national libraries or national bibliographic agencies, it is also addressed to university and research libraries, and can be used by other types of libraries and collections that have a wider choice and do not have the same responsibility of describing the national output or of sharing records. The ISBD aims to standardize the description and to be useful for all kinds of bibliographic communities at different levels of compliance. The standardization admits levels of degree. The international exchange of bibliographic information requires and takes benefits from maximum standardization of bibliographic description, but it could be considered excessive in some situations in which it is in conflict with the principle of user convenience. That is the

reason why the standardization must be flexible to adapt to the users of different types of libraries and also to local culture and script situations.

- “The descriptive elements needed to identify and select a resource are to be specified.”—This means that the description should include the elements that are significant to allow these actions and objectives. The principle requires a bibliographic description to be full enough to meet the objectives of a system for organizing information and, at the same time, allows other data elements to be optional. This principle could be considered sometimes to be against the principle of representation of the prescribed source that was the common practice of strict adherence to the title page until the revolution that represented the ideas of Lubetzky. He defended the logic of working having in mind the objectives that would determine the description:

our practice represents the result of an effort to preserve the integrity of the title-page and an inability to do so. Such effort may be justified in the cataloging of early books, where a difference in the title-page reflects a difference of edition, or in the cataloging of rare books, where the title-page has an interest of its own. It serves no purpose in the cataloging of modern books . . . In the cataloging of modern books the aim of the cataloger should be not to point out the differences of the title-pages but the identity of the books under them, so when a reader has reference to a given issue which may not be available he could safely be served by any other issue of the same edition.^[10]

This principle supposes a limit to a standardization that could be excessive. It is a practical action that reduces the needs for identification and selection of resources, and it was Cutter “one of the first to face the problem of necessary versus unnecessary data elements. He viewed appropriate fullness of description as a variable, depending on local needs and circumstances, such as library size . . . to the present day, but is becoming less useful as global cataloging renders distinctions based on library size irrelevant.”^[9]

- “The set of elements of information rather than their display or use in a specific automated system will provide the focus.” This principle represents the evolution of ISBD and the change of objectives since the beginning. It represents an intention of ensuring the interoperability with other systems’ displays. ISBD has been adapted to the current time, where many display formats coexist, usually locally developed. Some of them are suited to local users’ habits as it is the labeled display that is the most common and clear display for general end users in one language. ISBD, in addition to presenting an internationally understandable display, has introduced the necessary changes to allow consistency in other displays.

- “Cost effective practices must be considered in developing the stipulations.” This is the principle of economy by which, when there are alternative ways of achieving a goal, the less complicated one and the one requiring less time and effort will be preferred.

Although not specifically mentioned as a principle, the whole ISBD is a contribution to a principle of representation. “The distinctive feature of the ISBDs—that is, that the descriptive information is taken from the item itself in the form in which it is presented in that item—has been recognized as the most economical and more certain way of ensuring compatibility in bibliographic recording.”^[11] This representation principle does not necessarily mean transcription that is only required in area 1 with phrases such as “in the form in which it appears on the prescribed source of information,” or in area 2 or in area 6 including information not found on the prescribed source in square brackets (see section General Structure of ISBD for explanation of areas). The rest of the areas leave the cataloger the possibility of selection of elements in order to better achieve this representative description. At the same time it is necessary to ensure the accuracy of description and “to prevent idiosyncratic descriptions,” just in case this principle of representation if “carried too far would result in bibliographic descriptions that individually are correct but when taken collectively are inconsistent. It would go against the principle of user convenience . . .”^[12] If the information that is going to be transcribed could result in ambiguous, unintelligible, or incorrect data, this assessment must be explained and corrected, within brackets depending on the kind of information, to identify the resource clearly.

BASIS FOR DESCRIPTION: SOURCES OF INFORMATION

The data elements can be found in different places on a particular resource and can take different forms. Therefore, to reach consistency in description requires prescribing exactly where the elements can be taken from. Accurate description depends on the order of preference of sources of information on the resource, which means agreement on the specification of locations where an entity can represent itself.

The determination of sources varies depending on the type of material, but there are common characteristics for the determination: comprehensiveness, proximity, and persistence. This is clearly established in ISBD 0.4.1 Basis of the description: “For all types of material the resource itself constitutes the basis of the description” but specifically the criteria to determine a source of information is cited in 0.4.2.1 of ISBD. Although this stipulation is related to printed resources, it can be extrapolated to all: “The selection of the source to be treated as title-page

substitute is determined by considering which source has the fullest information, with preference given to a source that is part of the resource over sources outside the resource.” There is more reliability to internal sources than external ones that could be separated, modified, or lost. When use of internal sources is not possible, these criteria of persistence guide us to choose sources permanently associated with the resource.

Depending on the types of resources, with different physical characteristics, the sources will be different. In addition, the same works or content can be published in different physical formats, for example an e-book that is also in a format of a printed text, or can be published in more than one physical medium as kits or sharing characteristics of more than one, for example serially issued maps in electronic form. To solve this situation better and to accomplish one of the basic purposes of the ISBD, that is to facilitate record exchange, the ISBD urges national bibliographic agencies and libraries participating in networks to create separate bibliographic descriptions for works issued in multiple formats. Other libraries may select a single-record approach if they wish to do so.

Therefore, “the ISBD is applied to describe manifestations, by means of description of the item in hand as an exemplar of the entire manifestation, using *Functional Requirements for Bibliographic Records (FRBR) terminology*” (ISBD, 2007; viii). That conforms to the recommendation of the Statement of International Cataloging Principles:

2.1.1. Bibliographic records should typically reflect manifestations. These manifestations may embody a collection of works, an individual work, or a component part of a work.

Manifestations may appear in one or more physical units.

In general, a separate bibliographic record should be created for each physical format (manifestation).^[13]

GENERAL STRUCTURE OF ISBD

The ISBD is structured in eight areas with different kinds of content and with different interrelated data elements sequentially ordered. This arrangement corresponds to the order of relative importance of information that usually follows the order presented in the main sources of information. Its origin is the traditional organization that was found in the main resources at that time, books, and this was the order in which the information is presented on the title-page. The structure was accepted and standardized internationally because there was not much difference in such information in international practices, as many conferences on Universal Bibliographic Control would demonstrate. It was also accepted and adapted to other types or resources, as the publication patterns are common for the

majority of types of resources. The intention of arrangement of information following the patterns usually appearing in the resources is also for the users’ convenience, as it is the order in which they are accustomed to finding them. But at one time following the strict order of presentation on the main source, the transcription of the title page was expanded and was no longer helpful for the order of the catalog. Seymour Lubetzky well expressed that, “The problem with strict adherence to title-page sanctity in the organization of a bibliographic description is that it does not make for helpful order within a catalog. A well-arranged or integrated catalog requires that similar data elements appear in similar locations in bibliographic records.”^[14] This is accomplished with the logical and relative importance structure of the ISBD with the following areas:

Area 1—Title and statement of responsibility area

This area covers several data elements:

Title proper:

This consists of

the title of the resource in the form in which it appears on the prescribed sources of information for the title and statement of responsibility area. It includes alternative titles and the conjunction linking an alternative title with the first part of the title proper.

It can consist of a common title and a dependent title when a section, supplement, part, etc., has a title or designation insufficient to identify it without the inclusion of the common title or the title of the main resource.

(ISBD, 2007; 1.1-1.)

There are many stipulations to standardize the form of recording the title proper, or the selection of title proper when two or more titles appear on the prescribed source of information or when there is more than one prescribed source of information, about resources with two or more works with a collective title, or without a collective title, about resources that are part of another resource.

General material designation:

“The purpose of the general material designation is to indicate, in general terms and at an early point in the description, the class of material to which the resource belongs” (ISBD, 2007; 1.2-1). But to decide the class of material it is necessary to speak about the medium in which the manifestation is published, which is very important for organizing the collection. It is necessary to say whether it is computer-readable, microform, printed, etc.; and it is also necessary to indicate the way of perception by the user, tactile, three-dimensional form, etc.; and content characteristics, such as music or cartographic. An attempt has been made to address all these characteristics

with a common terminology used by the final user to categorize the resources, and much investigation on it is being made nowadays.

Parallel title:

“A parallel title consists of a title in another language and/or script than the title proper and presented as an equivalent of the title proper on the prescribed source(s) of information” (*ISBD*, 2007; 1.3-1).

Other title information:

“Other title information consists of a word or phrase, or a group of characters, appearing in conjunction with and subordinate to the title proper, parallel title(s) or titles of individual works contained in the resource” (*ISBD*, 2007; 1.4-1).

Statement of responsibility:

“A statement of responsibility consists of name(s), phrase(s), or group(s) of characters relating to the identification and/or function of any persons or corporate bodies responsible for or contributing to the creation or realisation of the intellectual or artistic content of a work contained in the resource described” (*ISBD*, 2007; 1.5-1). This information helps in the identification of the responsible entities of the work or expression, and at the same time reflects the relationship of those entities with the work or expression.

There has always been criticism against repetition of the author's name in the statement of responsibility in addition to its access point as the principal entry, but already in 1943 there were authors who defended that. “They maintain that a knowledge of the usage of the author's name on the title-page is sometimes helpful in the identification.”^[15] This reason continues to be equally important nowadays, because some usage forms are not clear enough to avoid the wrong attribution by the cataloger, in spite of the normalization of access points today which tends to accept the usage of authors. This mistake could not be mended without an accurate transcription of the statement of responsibility of the work as it appears in the resource.

Elaine Svenonius speaks about controlled versus uncontrolled vocabulary, the latter being “those that are derived as-is from documents containing information,” and the former “those that are assigned” and are controlled access points. “The dual representation serves to facilitate two different approaches to information: a keyword approach useful for identification and finding and a controlled-vocabulary approach required for collocation.”^[16]

The *ISBD* deals both with one statement of responsibility and with more than one statement of responsibility.

All these elements from area 1 are addressed in *ISBD* with its casuistry and stipulations relative to a transcription from sources of information for each element are given.

Area 2—Edition area

The edition statement is necessary for identification of the manifestation of a work. As said in the definition of the area “An edition includes all copies of a resource produced from substantially the same original input and issued by the same agency or group of agencies or a person. An edition may be identified by an edition statement on the resource or by information provided by the publisher” (*ISBD*, 2007; 2-1). We have to take into account the distinct publication patterns among countries in deciding when we have a real edition statement and not a reprint of the edition.

The edition area consists of the following data elements: the edition statement; the parallel edition statement, statements of responsibility relating to the edition; the additional edition statement and finally the statements of responsibility following an additional edition statement.

Area 3—Material or type of resource-specific area

This area is specific for particular classes of materials devoted to recording information that it is not possible to give in other areas because the data elements are different. Specifically it is to record information on the special music format; or mathematical data on scales, projection and coordinates and equinox for cartographic resources; and the numbering and dates of coverage of serials. As is explained above, nowadays there are resources that share characteristics from more than one type of resource, as for example a map serially issued, so this area is repeatable to allow giving the different data elements for specific resources.

Area 4—Publication, production, distribution, etc. area

The term “publication, production or distribution” is intended to cover all types of publication, production, distribution, issuing and release activities connected with resources (*ISBD*, 2007; 4-1).

In this area, with the issuing activities are recorded those data elements referring to activities of the process of physical manufacturing of the resource that can be developed by a different or by the same entity; in the last case only one statement is given. This area represents the integration of the common responsibilities of publication and of printing resources with financial and administrative responsibilities. But beyond, the activities of production include responsibilities of organization of the resource, fixing the data, and creative aspects, which are more common within electronic resources, motion pictures and sound recordings processes; and activities on making available the resource, i.e. its distribution.

The information recorded in this area has been related to, and considered representative of, the reputation of the resource, as the editor or producer is a guarantee of the physical quality of the resource and “the name of a

professional or scientific organization is an endorsement of the authenticity of the subject treatment.”^[15]

Therefore the data elements provided in this area to identify the entity that carries out this function are place of publication, production and/or distribution; name of publisher, producer and/or distributor; the statement of function of a distributor if required; date of publication, production and/or distribution; if printing information is given it is also necessary to give the place of printing, manufacture or engraving, the name of the printer, manufacturer or engraver and/or other printing information, followed by the date of printing or manufacture.

For those data elements the ISBD provides stipulations for cases when the information is in the resource and for cases when it is not in the resource. Stipulations for resources published in multiple issues or parts, or stipulations for procedures when there are irregularities in dates are given, because this information is very important for identification and selection.

Area 5—Physical description area

This area is reserved to describe the physical carrier of the resource, that is, to describe the copy in hand that we have as representative of the manifestation. But if for any reason these physical characteristics have been modified by any circumstances, the physical description continues referring to the manifestation that can be accessed not only in the collection of the library but also in other libraries or bookshops, etc., and the special peculiarities of the item in the collection should be explained in notes.

The detailed physical description has always been criticized as not necessary and less economic, but it is important information for library activities such as storage, circulation, and conservation.

In this area the data elements given are:

The specific material designation and extent: The specific format that belongs to the medium has been categorized in the GMD (General Material Designation) but here it is possible to use the more specific term best suited to the users. For this data element it is necessary to give stipulations when the resource is in one physical unit or when it is in more than one, or when it is a multimedia resource or kit. If the physical carriers can be counted, the number of units is given with the specific term for the carrier. It is followed by the extent, that is, the number of pieces it is composed of or the playing time. Extent-specific stipulations are given for specific types of resources.

Other data elements refer to other physical characteristics related to the method of production, illustrations, color, material from which the resource is made, etc. details that are not related to dimensions, which is the next data element defined, very useful for the management of space in the stacks, and can be used to help finding a resource being sought.

Finally an accompanying material statement can be added when appropriate. It represents a separate physical unit independent of the main carrier, and that is published

jointly with the resource as part of the manifestation but with a secondary role to the main work.

Area 6—Series area

“The series area is used when the resource being described belongs to a larger bibliographic resource: series, subseries or multipart monographic resource” (ISBD, 2007; 6-1). It represents the granularity in description. The resource as a whole could be described with the title of the series and the specific title proper of parts could be given in a contents note, or each part could be described by its title proper giving the “common title” of the work to which it belongs in the series statement in area 6. This convertibility is why this area and area 1 are so related, having almost the same data elements:

Title proper of series, subseries, or multipart monographic resource; parallel title of series, subseries, or multipart monographic resource; other title information of series, subseries, or multipart monographic resource; statements of responsibility relating to series, subseries, or multipart monographic resource. Because the resources belonging to series or subseries can be continuing resources, the data element of International Standard Serial Number of series or subseries is added. Finally the numbering of the separate resources within the series, subseries, or multipart monographic resource is included.

Area 7—Note area

The note area contains any descriptive information that has not been given in other areas of the description but that is considered to be important to users of bibliographic records. Notes qualify and amplify the description in areas 1–6 and can deal with any aspect of a resource. Notes may also give the bibliographic history of the resource and indicate relationships to other resources. (ISBD, 2007; 7-1.)

Most of the notes are optional and their use depends on the depth of description the library wants to make. But some of them are mandatory because they are fundamental for user access to the resource. An example would be the notes that specify the method of access to electronic resources. When the resource is direct access, the system requirements are specified, and when it is remote access the mode of access is specified, if possible providing the link. Another very important note for librarians looking for consistency in description is the one that specifies where exactly the title proper information has been taken from when the source is different from the prescribed source of information.

The notes are organized according to the ISBD areas, but in addition there can be other interesting notes not related to these areas but to description, bibliographic history, attribution of the work or expression, etc.

Area 8—Resource identifier and terms of availability area

A resource identifier is any number or alphanumeric designation associated with a resource according to an international standard, such as an International Standard

Book Number (ISBN) or an International Standard Serial Number (ISSN), or a designation assigned by a publisher. (*ISBD*, 2007; 8-1.)

The area is repeatable because one resource can have more than one identifier. For example in the case of multipart resources, each part can have its own identifier, and the whole resource can have another identifier.

In this area the following data elements are recorded when available: The resource identifier transcribed preceded, as appropriate, by letters that identify the standard; the key title assigned by the ISSN Network when the resource that is being described is a continuing resource; the terms of availability and/or price. When the identifier or the terms of availability or price need supplementary information, qualifications are given.

HISTORY AND RECENT DEVELOPMENT OF THE ISBD

Historically catalogs were lists of information to find a book in collections that essentially consisted of such types of resources. That is why the title page was used as the basis for cataloging, and the description of other types of materials had to fit into the book patterns.

Because the most important thing for finding a resource was to provide information on the author, the cataloger then gave more attention to find the authorship. The cataloging rules until the beginning of the twentieth century were mainly stipulations related to authorship. The other part of the cataloging was the description, but it was considered less important. First it was necessary to find, then it was possible to identify if the resource found was meeting the requirements that were looked for. As collections were growing, the identification needs were more important. This identification was only possible by means of the description of the resource. At this time the card catalog was considered a necessary intermediate tool. The rules for description had been influenced by the bibliographers who were developing their techniques for the description of older books, where the description should be as accurate as possible with close transcription of the title page from top to bottom. This exaggerated reverence for the title page did not allow catalogers to use a commonsense approach to late nineteenth century and twentieth century printed books.

Seymour Lubetzky was a figure who influenced many at this time presenting a

systematic approach, which took its departure from the assumption that before describing a book it is necessary first to be aware of the objectives that description is to serve. Only then is it clear what is and what is not to be included in a bibliographic record. . . . Basically their import was that a bibliographic description served first to identify a book and, secondly, to characterize its contents.

Data elements on a title page that did not further either of these objectives were to be excluded. . . . On the other hand, data elements that did not appear on a title page, yet were necessary to meet one or the other of the stated objectives of description, were to be included in a bibliographic record.^[17]

At this time, in the 1950s there was an unprecedented boom in book production. Trying to find a centralized solution to world bibliographic control, “UNESCO’s work was more realistically directed, based on two fundamental criteria, the first, concern for fundamental study and research, the second, reliance on national activities: ‘it is unrealistic to think progress in bibliographic control at the international level can be achieved even if national conditions are ignored. . . .’”^[18]

In 1958 the Symposium of National Libraries in Europe held in Vienna settled the basis for defining the role of the national library and its contribution to national bibliographic control by means of developing the current national bibliography.

According to the self-criticism environment on cataloging practices in the library community, IFLA (formerly International Federation of Library Associations) organized the International Conference on Cataloging Principles, in Paris in 1961. Preparatory to this conference, an examination of the problems relating to bibliographic control through the analysis of national cataloging codes was made. The conference supposed a landmark that had as a result an international agreement that influenced the cataloging codes world wide until today. But the principles accepted were again focused or centered mainly on access points, revealing the main concern at this time was not on description as the differences between countries were not considered important.

Eva Verona, Yugoslav librarian well known internationally for her work and her chairmanship of various IFLA committees and working groups, recognized this lack in her comments on the principles:

It might be argued that the list of elements specifying a particular book as given in section 2.1, and amplified in section 3.2 and section 6.4, is not complete. A complete list should necessarily include those particulars which enable the user of the alphabetical catalog to distinguish various editions of the same work. . . . It is thus made quite clear that the Statement is aware of the importance of such particulars in the alphabetical catalog. The fact that those particulars are not mentioned in section 2.1 in connection with the first basic function of the alphabetical catalog may be accounted for by the limitation of the Statement to problems concerning the choice and form of elements determining the order of entries.^[19]

But three things changed minds in 1960s: One was shared cataloging projects on a large scale; the other, the arrival of the computer.

As long as libraries were using computers solely for processing their own records there was no problem, but as soon as they began to exchange machine-readable records and tried to use those received from other agencies in their systems, the need for standardization became clear. Computers demand standards: standards for electronic storage and transmission, standards for the formats within which the data would be recorded and (to some extent) for the data content itself. The third factor was, oddly, a by-product of the International Conference on Cataloging Principles... the agreed text of the principles accompanied by full examples to illustrate them. Originally, the examples showed an embarrassing variety of descriptive practice beneath the agreed headings. ...^[20]

Work was started to prepare the second major cataloging conference of the period, the International Meeting of Cataloging Experts held in Copenhagen in 1969 at which was established the basis toward creating a system for the international exchange of information: The standard bibliographic description of each publication developed and distributed by a national agency in the country of origin of the publication, which will be responsible for creating records in such standardized conditions. The effectiveness of the system was dependent on the maximum standardization of the bibliographic description.

The study of the rules in use until that time revealed that there was sufficient similarity in the descriptive part of the catalog record as all the stipulations on description were to transcribe the title page. The main goal was, and continues to be, to offer consistency when sharing bibliographic information:

Under the title Universal Bibliographic Control (UBC) IFLA is proposing that UNESCO adopts as a major policy objective the promotion of a world-wide system for the control and exchange for bibliographic information. The purpose of the system is to make universally and promptly available, in a form which is internationally acceptable, basic bibliographic data on all publications issued in all countries.^[21]

In the promulgation of the UBC program three international organizations have played a major part: IFLA; the UNESCO General Information Programme (PGI); and the International Organization for Standardization (ISO). The international office for UBC was created, and it gave support at a variety of levels to projects directed toward its development. In so doing it has provided support to IFLA working groups and to experts engaged in particular bibliographic projects. Nowadays it has been supplanted by ICABS IFLA-CDNL Alliance for Bibliographic Standards. (ICAB's Web page, available at <http://www.ifla.org/VI/7/icabs.htm> (accessed October 2007). The National Library of Australia, the Library of Congress, The British Library, the Koninklijke Bibliotheek, and Die Deutsche Bibliothek have agreed to participate in a joint alliance together with the Biblioteca Nacional de Portugal, IFLA and CDNL to assure ongoing coordination, communication

and support for key activities in the areas of bibliographic and resource control for all types of resources and related format and protocol standards.)

Its objectives at that time were not much different from objectives today (related above):

1. The interchange of bibliographic records.
2. Interpretation of records from foreign sources and ability to identify the parts of the record, independent of the language and script.
3. Conversion of manual records to electronic form.

There were three methods to achieve these: definition of elements, organization into a structure in eight areas, and identification of each element by a symbol of punctuation.

IFLA's special contribution to the concept of UBC is its firm belief that every country can become a component part of the UBC system, that each has a contribution to make. It accepts that contributions may vary considerably in quantity between developed and developing countries ...^[22]

Among the requirements to achieve UBC there were the establishment of the national bibliographic agency in charge of preparing the authoritative bibliographic record for each new publication issued in the country and collected in national bibliographies; the record's acceptance at an international level; and also an international standard for creating the bibliographic records. That standard must take into account: (1) its contents: the elements to be included in the authoritative record; the order of those elements; the means of distinguishing the elements and their functions; and (2) its physical form; compatibility of machine-readable records; standardization of catalog cards.

The basic premise for establishing UBC has been set out thus: that the comprehensive bibliographic record of a publication is made once in a country of its origin, in accordance with international standards which are applicable in both manual and mechanized systems; and that record is then available speedily, in a physical form which is also internationally acceptable.

The detailed elements that make up that comprehensive and authoritative bibliographic record include all the information about the publication which may be required to fulfill any of the functions of library or information services. The selection of these elements and the way in which they are presented have evolved from careful work of experts. ... there are still areas of national bibliographic traditions evolving from language and culture.^[23]

This is mainly the reason why the ISBD was designed primarily for national bibliographic agencies that are responsible for creating descriptions with all the defined mandatory elements, as was explicitly said in the introduction. But this practice is also recommended for libraries that exchange bibliographic records. Other libraries can use the ISBD, and it is recommended that they do, but

they can adapt it to their needs, selecting the elements to be described. The reason is that the ISBDs were intended to serve as a principal component of IFLA's program to promote UBC.

The first of the ISBDs to be published was the International Standard Bibliographic Description for Monographic Publications (ISBD(M)), which appeared in 1971, with a revised text published in 1974 as the "first standard edition." It was clearly based on traditional descriptions of monographs found on printed catalog cards. Other ISBDs subsequently appeared for specific types of resources: ISBD(S) for serials was also published in 1974; ISBD(CM) for cartographic materials and ISBD(NBM) for non-book materials were both first published in 1977; ISBD(A) for older monographic publications (antiquarian) and ISBD(PM) for printed music first editions were published in 1980; and the ISBD(CF) for computer files, first edition, was published in 1990. Along the way, the need was felt for a general framework to which all the ISBDs would conform, resulting in production of the ISBD(G) published in 1977; the primary utility of the ISBD(G) was that of ensuring harmony among the other ISBDs. For article-level publications, *Guidelines for the application of the ISBDs to the description of component parts* was issued in 1988. For a more detailed introduction to the ISBDs, see Byrum.^[24]

It was necessary to normalize the description of each type of material, but today the borders are not so clear.

At the IFLA World Congress in Brussels, held in August 1977, the Standing Committee of the IFLA Section on Cataloging made important new decisions in relation to IFLA's program of ISBDs. It was decided that all ISBD texts would be fixed to a life of five years, after which revision would be considered for all texts or for particular texts.

More pragmatically, they have been revised as the need has arisen, to implement general applicable changes or by the evolution of library materials, such as those that resulted in publication of the ISBD for electronic resources and, more recently, the ISBD for serials and other continuing resources.

Although some ISBDs have been developed or revised to meet particular needs, there have been two overall revision projects affecting the entire family of ISBDs.

First General Review Project

Consequent to the decision taken in 1977, mentioned above, the initial overall revision resulted in the creation of the ISBD Review Committee, which first met in August 1981.

The committee established three major objectives for the first general review project:

1. To harmonize provisions, achieving increased consistency.

2. To improve examples.
3. To make the provisions more applicable to catalogers working with materials published in non-roman scripts.

In addition, two narrower objectives motivated this particular revision effort:

1. To review the use of the equals sign (as its use in bibliographic descriptions had been the source of some controversy).
2. To remove coverage of machine-readable materials from the ISBD for nonbook materials.^[25]

By the early 1990s the revised edition of the ISBDs had been published:

- The standard for monographic publications ISBD(M) previously revised in 1978, was revised again in 1987.
- Cartographic materials ISBD(CM) was revised in 1987.
- Nonbook materials ISBD(NBM) was revised in 1987.
- Serials ISBD(S) was revised in 1988.
- Printed music ISBD(PM) was revised in 1989.
- ISBD(G) was revised in 1992.
- In addition, a separate ISBD was published for computer files (1990), which, due to the rapid advances in technology, was soon superseded by creation of an ISBD for electronic resources (1997). (The entire list of ISBDs is available at <http://www.ifla.org/VI/3/nd1/isbdlist.htm>, (accessed October 2007).

Second General Review Project

In the early 1990s, the section on cataloging in cooperation with other sections set up the Study Group on the Functional Requirements for Bibliographic Records (FRBR). One immediate consequence of this development was the decision to suspend most revision work on the ISBDs while the FRBR Study Group pursued its charge to "recommend a basic level of functionality and basic data requirements for records created by national bibliographic agencies." This decision resulted in the permanent suspension of a project to identify the components of a "Concise ISBD(M)," because it was expected that FRBR's findings would, in effect, provide such a baseline. In 1998, the FRBR Study Group published its final report,^[26] and the ISBD Review Group was reconstituted to initiate a full-scale review of the ISBDs in order to implement FRBR's recommendations for a basic level national bibliographic record^[27] and ensure conformity between the provisions of the ISBDs and FRBR's data requirements.

To facilitate the work of national bibliographic agencies of preparing the definitive description containing the mandatory elements, the ISBDs designate as "optional" those data elements that are not mandatory when applicable or as "conditional" those data elements that are needed in certain

circumstances but may otherwise be considered optional. Therefore, the main task in pursuing the second general review entailed a close look at the ISBD data elements that were now mandatory in order to ensure that no element that was mandatory in FRBR was optional in the ISBDs.

Another important task was consideration of the adaptation of ISBD terminology to FRBR's terms "work," "expression," "manifestation," and "item" to determine if they should be introduced in place of terms such as "publication" or "item." The Review Group concluded that it was essential for IFLA to clarify the relationship between the ISBDs and the FRBR model. The group encountered difficulties in trying to achieve that alignment, in large part because the terms used in FRBR were defined in the context of an entity-relationship model conceived at a higher level of abstraction than the stipulations for the ISBDs. While the entities defined in the FRBR model are clearly based on the elements forming an ISBD description,^[28] the relationships are too complex to be conveyed through a simple substitution of terminology. Taking into consideration Patrick Le Boeuf's advice at the Frankfurt IME ICC (International Meeting of Experts on an International Cataloging Code) in his paper on "Brave new FRBR world":^[29] "FRBR terminology should not be merely incorporated such as it stands into the ISBDs and cataloging rules, but [these] should keep their own specific terminology, and provide accurate definitions showing how each term in this specific terminology is conceptually related to the FRBR terminology." The Review Group thus decided that the development of a table to detail the relationship of each of the elements specified in the ISBDs to its corresponding entity, attribute or relationship as defined in the FRBR model, would satisfy the need to make clear that the ISBDs and FRBR themselves enjoy a harmonious relationship.^[30]

Nevertheless, the ISBD Review Group did decide to introduce some changes in terminology, beginning with the recently revised ISBD(G). Among them is the use of the term "resource" rather than "item" or "publication." This decision was taken because the use of the term "item" in the ISBD was different from the term "item" as used in FRBR, and it is difficult not to confuse them.

Some of the ISBDs (G, M, CR, ER, CM, and A) went through this revision process, but the process was interrupted before being finished, as work on the consolidated ISBD began.

Reasons for a Consolidated ISBD

There had been seven specialized ISBDs, plus the General ISBD. These ISBDs have been revised and published at various times, with no method for incorporating changes made in newer texts that affect all the ISBDs into the older texts. For example, when it was decided to incorporate decisions on which data elements should remain mandatory in the ISBDs based on those required in FRBR, these

changes were incorporated into the ISBD(M) and the ISBD(CR) that were issued in 2002, and the ISBD(G) in 2004 although they applied to all of the ISBDs.

In addition to this situation, publications that show characteristics of more than one format require the application of stipulations from more than one ISBD. Because the ISBDs themselves had some inconsistencies, this brought major difficulties that caused the ISBD Review Group to decide in 2003 that consolidation of the ISBDs was feasible, and work was started on preparing a definitive text.

The work received ICABS support for a first merger of the text of the seven ISBDs. Project money was also granted by the IFLA Professional Committee.

A "final" version was sent to the IFLA Cataloging Section's Standing Committee, which voted for acceptance before the end of March of 2007. The consolidated ISBD replaces the specialized ISBDs.

In the integration of information from all types of resources, agreement was reached on the general outline to be followed for each area. In addition, it was decided to recommend that:

- The structure should be changed to a new structure of areas where general stipulations that apply to all types of resources are given first, followed by exceptions or additional stipulations that are needed for specific types of resources.
- Present stipulations should fit into the new structure; therefore, the order of stipulations has also been modified to make the text more logical and consistent.
- Some changes should be made to generalize wording and to match wording as much as possible, also taking into account the stipulations that were considered mandatory, conditional, or optional in the already-revised ISBDs.
- The GMD should be moved from after the title proper to another location.
- Further changes to stipulations can be made at a later stage.^[31]

The focus has been on the set of elements of information rather than their display, and looking for interoperability with other systems and display formats, the punctuation has been slightly changed. Although the importance that ISBD punctuation has had in the past and continues to have in the context of different languages and scripts is recognized, the presentation of information is a secondary objective. In local catalogs the labeled display is now the most common and clear display for many users, that is why punctuation is not as essential as before but continues being recommended for international understanding.

CONCLUSION

The UBC concept continues to provide a foundation for the international and national organization of the creation

of bibliographic data. "Among the characteristics of a national bibliography are that it provides a current, timely, comprehensive, and authoritative list of all titles published in a country, it provides a record of their existence, and it identifies them unambiguously."^[32] The ISBD helps in providing authoritative bibliographic records, but the ISBD has spread far beyond because in the management process of our collections it is easy and cheap to copy bibliographic records or download them from other databases and use them with scarcely a need to make changes. For this reason and because the process of reviewing the ISBD will continue to keep it updated to take account of new developments, the ISBD will continue to be the standard for definition elements and descriptive content of bibliographic records.

Design Science in the Information Sciences

Judith Weedman

School of Library and Information Science, San Jose State University, Fullerton, California, U.S.A.

Abstract

Design is a core professional responsibility in the information professions as in others. It may be local and idiosyncratic, or it may be the focus of a major research project. Design researchers have argued that there are fundamental design problems and design solutions that cross scale and domain boundaries; if this is so, then design science, the study of design, should build knowledge both about particular domains and also about what is true across domains. This entry examines design science in several fields to indicate where it might inform design in the library and information sciences. It concludes with two examples from the information sciences, one a design science study of vocabulary design and one a design research project, in which the research consisted of design of an information retrieval system.

INTRODUCTION

Design is a central professional task in the library and information science (LIS). Patrick Wilson wrote in 1996 that information science inhabits two fields, engineering research and development (R&D) and social/behavioral/humanistic studies. In R&D, Wilson included both the design of material technologies for information retrieval and the design of intellectual technologies such as metadata systems and strategies for searching information retrieval systems. Thirty years earlier, Herbert Simon, in his influential *Sciences of the Artificial*,^[1] wrote that design is the core responsibility in all professions. Simon defined design as taking a problematic situation and transforming it into a desirable situation. Management decision-making, strategic planning, psychotherapy, and other nonmaterial problem-solving are thus included as design work, along with material design such as engineering, sculpture, and architecture.

Design science is the study of the work of design—how designers make decisions, use tools, manage problems, and think about their work, and what the characteristics of that work are. Research methods include interviews, surveys, ethnographic techniques, introspection, and philosophical investigations. One area of design science has been referred to as “design research” (or sometimes “design science” or “design science research”); this refers to the practice of design in which novel and important design is undertaken for the combined purposes of creation of the artifact and contribution to the professional knowledge base of the field.^[2]

Design is under-theorized in the library and information sciences. On the R&D side of the disciplines, there is a well-developed line of research in which information retrieval design is treated as an experimental science (thanks in large part to the efforts of Gerard Salton). However, there is little or no theory about the work of design

itself. The social science side of LIS has concentrated on users of information systems—information-seeking behavior, user satisfaction, search behaviors of experts and novices, sociotechnical studies of digital library use, etc. Although the understanding of the technical differences between information retrieval (IR) systems is important to understanding differences in user behavior, the characteristics of IR systems has rarely been an independent variable in research. Nor has the social science tradition in LIS often studied the processes by which technical systems are designed. The presence of both research traditions within the field could provide a “home field advantage” over disciplines where a social understanding of technical systems requires either importing ideas from outside the domain proper or the importing of social scientists themselves. Use of design science as a social science approach could create interesting connections between the social science and engineering sides of the discipline, as well as adding a dimension to the study of how information and social systems interact. Conceptualizing the sum of the design work undertaken in our field as “design research” could add dimensions interesting from both social science and technical design standpoints.

Buchanan^[3] notes that each of the fields that have studied their own design work has tended to regard it “as an applied version of its own knowledge, methods, and principles” (1995a, p. 18). The various literatures have had little cross-boundary interaction; the notable exceptions are Simon (artificial intelligence) and Alexander (architecture). There is a growing belief, however, that there are similarities in design problems and solutions that cross domains, and some research to determine whether that is in fact the case.^[4] Thomas and Carroll argue that design is a way of looking at a problem and is therefore not exclusive to a particular kind of problem; they found that “activities as diverse as software design, architectural design, naming, and letter-writing appear to have much in common.”^[5] Nigel Cross, who has

written extensively about design methodology and design theory, also asserts that design is at least partially independent of the profession in which it is undertaken and that there exists a form of knowledge which is a “designerly way of knowing.” In 1982, Cross^[6] called for the construction of a way of conversing about design that is domain independent. It is in this spirit that this entry will draw attention to several strands of literatures from various disciplines. The goal is to highlight themes and approaches that may be of use to researchers or practitioners interested in applying them in the library and information sciences.

In everyday conversation, “design” is often equated with “style”—extra, nonfunctional aspects of a product that make it attractive or fashionable or characteristic of a particular approach; this is not the meaning used here. Design in this entry refers to the professional or research activity that results in a plan for a product or service that will be or could be instantiated in the world to solve a problem. Designing often includes the actual creation of the product or service, but as Schon notes,^[4] designers often create blueprints or sketches or combinations of functions which someone else will turn into a building or landscape or software code. In some fields the distinction between design and making is theoretically important, with design as an intellectually different activity from that of instantiating the design.

Design takes place in a range of professions and a range of venues. Buchanan,^[7] for instance, divides the “design professions” into four general groups: 1) those that design symbolic and visual communications (graphics, books and magazines, film, computer display, etc.); 2) those that design material objects (clothing, tools, instruments, machinery); 3) those that design activities and organized services (management functions of logistics, decision making, strategic planning); and 4) those that design systems or environments (systems engineering, software design, architecture, and urban planning). Information professionals and researchers work in all four of these categories.

Two assumptions underlie this entry. The first is that there is indeed some “designerly way of knowing” that crosses disciplinary and professional boundaries. The second is that every design context is different, with unique interactions between context and process. The uncertainty in design is a constant in design theory. After an exploration of this core concept, the following seven sections address additional aspects of design work that seem to be independent of the particular physical or intellectual artifact being designed. An example of design science and an example of design research in library and information science are then described.

UNCERTAINTY

That design practice is inherently uncertain because it involves changing potential into actuality is a key factor

addressed by most design theories. In this entry, it is given pride of place, discussed first and then pervading discussion of other aspects of design.

Historically, two responses have been made to uncertainty, attempts to remove it from design or acknowledgment of it as an inherent part of the creative process. The first, in part a reaction to an earlier tendency to romanticize inspiration and individual creativity, was to find objective and rational techniques that would remove uncertainty and allow the development of methods that would give reliable results. The second, in part a reaction to the rationalists, was to acknowledge that uncertainty is not removable and to embrace it as a part of the creative process. The first philosophy can be traced back to the logical positivists, the second to the constructivism of John Dewey and Charles Sanders Peirce.

The movement to develop design techniques that removed the mysterious, inexact, intuitive component and make design more like science began in the early twentieth century. The term “design science” itself is a direct descendent of this attempt, though it is also used today by those who reject the desirability of objective, rationalist methodologies. The architect and urban planner Le Corbusier was a pioneer in developing Modern Architecture theory for the building of spaces; he began his work during the First World War, when the traditional European city was showing the destructive effects of the Industrial Revolution. Believing that improving living spaces would allow people themselves to improve, he sought techniques that would create both harmony and efficiency in the built environment. Harmony could be achieved by the application of Leonardo da Vinci’s golden ratio which based building proportions on the proportions of the human body and by the incorporation of concepts about the mathematical order of the universe. Uncertainty was addressed with techniques based on the objective, rational industrial management ideas of F. W. Taylor and Henry Ford. “The use of the house consists of a regular sequence of definite functions. The regular sequence of these functions is a traffic phenomenon. To render that traffic exact, economical and rapid is the key effort of modern architectural science” (Le Corbusier, cited by Cross).^[8]

Like Le Corbusier, Buckminster Fuller believed that design of buildings and spaces based on rational principles rather than aesthetic inspiration would solve many contemporary problems. He is thought to have originated the term “design science,” which he defined as “effective application of the principles of science to the conscious design of our total environment in order to help make the Earth’s finite resources meet the needs of all humanity without disrupting the ecological processes of the planet.”^[9] He declared the years between 1965 and 1975 the Design Science Decade, and urged a retooling for schools of architecture around the world, to use scientific methods to “measure, observe, and improve solutions until

solutions are developed that will work not just once, but over and over, and in a variety of situations.”^[10]

The architect Christopher Alexander^[11] also sought to develop systematic design methods that would give reliable outcomes; he explored the use of logic and mathematics, and later computers, to analyze the uncertainty out of design problems. While he saw a role for intuition, he argued that many had made a fetish of it, and that too much emphasis on intuition and artistry prevented the designer from asking reasonable questions and employing systematic processes. The increasing complexity of design problems required rational methods. A design problem “has requirements which have to be met and there are interactions between the requirements, which makes the requirements hard to meet. . . . Each of the issues interacts with several of the others . . . [In large design problems], each issue is itself a vast problem; and the pattern of interactions is vastly complicated.”

In his 1964 book *Notes on the Synthesis of Form*, Alexander^[12] asserts that most design problems are so complex that the designer cannot see the solution. Therefore, the architectural designer should start by listing all of the requirements and their interactions with each other. Once this is done, the requirements can be broken down into subrequirements; the solutions for each of the subrequirements will then be easier to determine, and from the set of solutions to the subrequirements, the final form can be synthesized. Thus the process is to apply the logic of analysis first, to determine all the parts of the whole, followed by applying the logic of synthesis to combine the solutions. In *A Pattern Language*,^[13] Alexander and five coauthors systematically analyze common problems in design and then describe the core of the solution to each problem, providing patterns that can be combined and recombined to solve architectural problems ranging from the level of climbing plants, doors, windows, and duct space through the level of rooms and foundations to entire buildings, towns, and the distribution of towns. Over time, as his ideas and others of the rationalist approach became more widely accepted, Alexander came to feel that just as people had made a fetish of individual intuition in design, so they were now making a fetish of a rationalistic methods. Disavowing what he described as a “painful and drawn-out misunderstanding” of his work, he disassociated himself from the use of method for its own sake, which he felt had become desiccated, dried up, and senseless.

Herbert Simon is the most-quoted and most influential rationalist, objectivist theorist today. In his 1969 book *The Sciences of the Artificial*,^[14] he argues that design is a process of decomposition; the problem is defined, alternatives are generated, and the alternatives are tested against an array of requirements and constraints, often in nested series of cycles. Much like Alexander, he argued in “The Structure of Ill-Structured Problems,”^[15] written for the artificial intelligence community, that large, ill-structured

problems can be broken down into smaller problems which are structured and therefore solvable.

In the reaction against the rational approach and attempts to decompose messy problems into solvable ones, one of the most influential writers has been Horst Rittel. He began developing the concept of “wicked problems” in the mid-1960s. Rittel took the phrase from Karl Popper, but used it differently. Wicked problems are ill-defined, and Rittel denies that they can be analyzed into smaller, well-structured problems. Published in an urban policy journal, Rittel and Webber’s “Dilemmas in a General Theory of Planning”^[16] defined wicked problems as those which are ill-defined, messy, circular, and aggressive. “Tame” problems are definable and separable and may have solutions that are findable; in addition, it can be determined whether or not the problem has been solved. Chess, puzzle-solving, and math are examples of tame problems. With wicked problems, “one of the most intractable problems is that of defining the problem (of knowing what distinguishes an observed condition from a desired condition) and of locating problems (finding where in the complex causal networks the trouble really lies). In turn, and equally intractable, is the problem of identifying the actions that might effectively narrow the gap between what-is and what-ought-to-be.”^[17] Rittel and Webber list ten distinguishing properties of wicked problems:

1. There is no definitive formulation of a wicked problem.
2. Wicked problems have no stopping rule.
3. Solutions to wicked problems are not true-or-false, but good-or-bad.
4. There is no immediate and no ultimate test of a solution to a wicked problem.
5. Every solution to a wicked problem is a “one-shot operation”; because there is no opportunity to learn by trial-and-error, every attempt counts significantly.
6. Wicked problems do not have an enumerable (or an exhaustively describable) set of potential solutions, nor is there a well-described set of permissible operations that may be incorporated into the plan.
7. Every wicked problem is essentially unique.
8. Every wicked problem can be considered to be a symptom of another problem.
9. The existence of a discrepancy representing a wicked problem can be explained in numerous ways. The choice of explanation determines the nature of the problem’s resolution.
10. The planner has no right to be wrong.

Today many design theorists see the unexpected as the source of, or opportunity for, creativity. Donald Schon, a philosopher who developed an epistemology of professional practice, accused rationalist theories of being radically incomplete. He studied six different professions for his 1983 book, *The Reflective Practitioner*.^[4] architecture,

clinical psychology, engineering, scientists designing equipment to test their hypotheses, city planning, and management. Like Simon, he saw design as the core of professional practice, but when he actually studied professionals at work he found that they were not carrying out series of logical transformations until the problems were solvable, but rather making and remaking entire design structures. Well-formed problem-solving of the sort advocated by Simon occurred only in later stages, after the design structure had stabilized. In the early stages, he found very fluid activities which often resulted in surprise and learning. A second problem that Schon found with the rationalist tradition was that it could not account for this kind of learning, which often results in reframing the problem itself. The third problem was that Simon and others tend to regard rational decision as a process that occurs within the mind of an individual; Schon observed, to the contrary, that designing is almost always a social process, with constraints and affordances arising from colleagues, the customer or imagined user, funding agencies, management structures, designers of the technologies the designer uses, distributors of materials, and so on.

Other researchers have supported the idea that the presence of the unexpected benefits design as well as creating problems. Bucciarelli,^[4] writing of product engineering, found that uncertainty actually allowed participants to exercise their creativity, that a variation untried before or challenging an assumption or constraint took engineers into unknown areas, where outcomes were unpredictable. Organizational war stories and jokes about Murphy's law reflect a design culture's realization that in design there is always disorder, chance, the creative, surprise—the unknown. Gasser,^[18] in a forum on management as design, wrote that

randomness is a natural consequence of engagement with the world. The more engaged an actor is, the more apparent randomness, uniqueness, or 'situatedness' he or she experiences. To be engaged in a present experience means to be able to differentiate that present experience from another—to experience its uniqueness, its lack of pattern with respect to other situations. . . . Deliberate injection of randomness can be a powerful tool for analysis and even for improving efficiency of certain activities and processes.

PROBLEM SETTING

Simon's^[15] argument that design problems which are ill-defined in the beginning can be broken down into smaller well-defined problems is undermined by many authors' descriptions of the problem-setting process. Rittel and Webber begin defining wicked problems with the characteristic that "there is no definitive formulation" of the

problem. Others argue that it is not just wicked problems for which this is true, but that in fact all true design shares this characteristic. Lave,^[19] writing of problem-solving in general, argues that problems are generated in relation to the particular setting within which the practitioner is working, and that problem solvers choose "whether to have a problem or not, and the specification of what constitutes the problem." Even in an engineering firm where the task is to design to client specifications, Bucciarelli asserts, they are negotiating the nature of the problem with the specifications themselves, with the suppliers of materials, with the nature of the tools they have available, and with others on the design team, and of course with the clients.

There is a large literature on client or user participation in design and the difficulties in such collaboration. Many authors of works on information systems have discussed the problem of obtaining useful information from potential users about what the problem is and what the solution should be—much of users' knowledge is tacit, and they lack the design and technical knowledge to understand the kind of information that designers need; designers, on the other hand, often lack thorough understanding of users' work and workflow despite time spent in requirements elicitation.^[20] Thus the negotiation about what the artifact will be has many dimensions and generally goes through many iterations; it is frequently the case that users and designers think they agree, only to discover later that words had disguised the tacit understandings of each side and that in fact they were operating under very different assumptions. In addition, design projects are often set in motion by the supervisors of those who will actually use the artifact to accomplish their work, which adds additional layers of definition which affect the understanding of the need the project addresses.

Boland^[21] stresses the impact of language on problem definition; writing of business managers as designers, he says "Good designers are aware of their own vocabulary and what it does to their work. . . . How we describe what a manager is and what he should do, what a problem is and how it should be approached, and what a good and true course of action is and how it is to be achieved, are all dependent upon our vocabulary." Schon^[22] similarly argues that "When we set the problem, we select what we will treat as the 'things' of the situation, we set the boundaries of our attention to it, and we impose upon it a coherence" 1983, p. 39.

One of the sources of uncertainty at the stage of problem definition is constraints—how needs will be ascertained, with whom, how they will be understood and then translated into design concepts, what materials and processes are both available and judged appropriate, which outcomes are required and which are secondary. The definition of constraints contributes to how a design problem is defined and therefore to how it is solved. Vincenti^[23] studied events in the history of aeronautical

engineering; he asserts that although most of the work is done at the lower levels of design, the top level of problem definition, which is where the problems are primarily conceptual and unstructured, is where knowledge growth occurs in engineering.

CONVERSATIONS WITH MATERIALS

Some of the uncertainty of design results from the interaction between designer and the materials of design. Wagner^[24] says that architects “meander” between seeing specifications and fixed elements of a solution precisely, and seeing them as partial and preliminary, still in formation. Schon^[4] calls this a “conversation with the materials” of design, in which the designer makes a move and the materials “talk back.” The designer then adapts as she sees how the materials respond to her, and they in turn respond to her adaptation. Keller and Keller^[25] in an essay titled “Thinking with Iron,” describe the way that a blacksmith takes an action with the fire and metal and the iron responds; the blacksmith then responds to that result, undoing the action or deciding what next action the response has made appropriate. Through this conversation, the design emerges. Although the blacksmith has begun with a general plan, the specific actions and the plan itself become fluid and may change as his actions change the situation.

Often the early conversations are carried out in “virtual reality.”^[4] Rather than jumping directly into the creation, designers often test their ideas using sketches, computer graphics programs, conversations, and other substitutes for the actual materials. As noted above, it is critical that the virtual medium be sufficiently indeterminate to allow surprises to occur, for the designer to learn from the actions he takes. Art historian Rudolf Arnheim quotes Goldschmidt as describing sketching as a dialectic process. Sketches are not just a representation on paper of the images in the designer’s mind; rather, they are an oscillation of arguments and the responses of the sketch, in which the sketch supplies essential new food for the arguments.^[26]

Another representation of this process is as experiments testing hypotheses, each of which is evaluated for fit and misfit, and changes the context in which the next hypothesis and test will be carried out.^[27] Similarly, Wagner^[24] describes this oscillation as the underpinning “for the passage from possibility to actuality which is the work of design.”

Rationalist theorists of design have described such tests as running a maze, with the assumption that although many trials may be dead ends, eventually the correct path will be found and design will proceed. Schon, however, asserts that a designer can never make a move which has exactly the intended results, and that her knowledge about what is possible and desirable evolves as the materials of

the situation talk back to her. It is as though the process of running the maze *changes* the maze.

CONSTRAINTS

Constraints enable the definition of a problem and the range of solutions, and also limit them. Standards, codes (such as construction codes), consideration of “best practices,” textbooks, and other formal sources of professional knowledge provide guidance. Current consensus about good design stimulates and provides direction to creative ideas. Codes are interpreted and conformed to in different ways; relationships between stakeholders are defined and redefined as the design situation evolves. Experience with a standard can be fed back into the system and the standard be rewritten.

Other constraints arise from the specifications for a project, as noted above. Time and money also influence design decisions. Organizational culture about how projects should be carried out may determine the approaches at both unconscious and conscious levels.

The materials of design, both the tools and the “raw material” also provide opportunities and limitations. Architects work explicitly with the constraints provided by land, soil type, and climate conditions. Schon^[28] quotes an instructor in a school of architecture as advising a student to “let the land generate some sub-ideas” (p. 89). Reciprocal transformations between the designer and the field of constraints give shape to a design project.

TOOLS

Traditionally, the tools of design have often been ignored or seen simplistically as enabling or imposing limitations on the process. However, theorists in sociotechnical studies emphasize the importance of paying serious scholarly attention to *all* of the elements of a research (or design) situation if we are to eventually understand the process. Clarke and Fujimura^[29] explore the idea of “the right tool for the job.” Griesemer^[30] in that volume makes the point that the tools the scientist understands to be appropriate shape the problem as well as the solution. Collopy^[31] notes that an important difference between expert and novice designers is that novices do not fully understand the control that they could have over the design environment itself. Experts have learned how to design tools that help them to think of things that they would not normally; tools are tools for thought as well as for material actions. Wagner^[24] describes ways in which design labs are often constructively cluttered, filled with toys, gadgets, interesting shapes, all tossed around somewhat arbitrarily; unfamiliar juxtapositions of objects can give rise to creative leaps, juxtaposing ideas about the artifact in ways that give new direction.

Schon^[4] gives special attention to the tools that create what he calls virtual worlds—these include maquettes, scale models, rehearsals, improvisations, computer simulations, and so on. He identifies this process in architectural design studies where sketching is the basis for communication between student and instructor and also in the relationship between a psychologist and patient where transference and counter-transference serve as a substitute for firsthand experience, a virtual world which represents the patient's other relationships and which can be analyzed to understand the meanings and effects of action. Boland and Collopy^[32] describe an architect's model as a tool for thinking, a stimulus and a way to explore ideas, not as a representation of a future reality. They argue that in management, models are taken too seriously, as a kind of compressed truth, and urge managers to break loose from "decision attitudes" and foster instead "design attitudes."

Henderson^[33] found in an ethnographic study of industrial engineers that use of computer graphics in design often could not accommodate uncertainty, and too quickly drove the engineer to settle on an approach. Therefore engineers often mixed paper practices with their electronic practices to protect the cognitive spaces where creativity took place. Creative design work is based, she found, on unarticulated knowledge, often visual in format; and this knowledge is recalcitrant to incorporation into computer graphic systems. Attfield et al.^[34] note similar phenomena, and add that uncertainty is particularly important during the early stages of the design process. Boland and Collopy^[32] as well describe an architect shaping his design ideas with his hands and materials, and using software only much later. The value of virtual worlds is in their malleability; when they remove uncertainty prematurely, they limit the range of potential problem solutions.

DESIGN FAILURE

One of the consequences of the presence of the unexpected, of course, is failure. According to David Pye (cited by Petroski,^[35]) there is always compromise in design.

The requirements for design conflict and cannot be reconciled. All designs for devices are in some degree failures, either because they flout one or another of the requirements or because they are compromises, and compromise implies a degree of failure. . . . All designs for use are arbitrary. The designer or his client has to choose in what degree and where there shall be failure. . . . It is quite impossible for any design to be 'the logical outcome of the requirements,' simply because, the requirements being in conflict, their logical outcome is an impossibility (pp. 217–218).

And, somewhat paradoxically, failure is a major contributor to the reduction of the unexpected. Henry

Petroski,^[35] writing about structural engineering, points out that all possible uses of a structure under all possible conditions can never be anticipated. Structural engineering is hypothesizing, testing one's expectations of how things will work. Engineering design is revising, analyzing by questioning the behaviors of the parts under the imagined conditions of use, discovering problem areas, redesigning, and then analyzing the new design. Prototyping is one method of hypothesizing, allowing the designer to "fail early," and without consequence. The process continues until the designer can imagine no possible way in which the structure can fail under the anticipated use. But the uncertainty is always present. The less like the past the future is, the less likely that the engineer's hypotheses will be correct; and the object itself changes the future. Although an incorrect hypothesis may hold for a long time without discovery under certain conditions, if those conditions are no longer met, the conditions under which the hypothesis fails may be revealed.

"The well prepared engineer can and does build beyond experience."^[36] Copying structures which have stood the test of time is engineering work that holds no distinction; Petroski compares engineers with artists: "just as the great writers are those who have given us unique and daring experiments that have worked, so it is that the great engineers are those who have given us their daring and unique structural experiments that have stood the test of time."^[37] An engineer designing beyond his knowledge or ability is violating ethical principles, with potentially catastrophic results; but "failure in innovation should be no more opprobrious to the engineer who has prepared himself as well as he could for his attempt to build a longer bridge than to a pole vaulter who fails to make a record vault after practicing his event and using his pole to its capacity."^[35]

Although failure of an engineered structure can be tragic in its consequences, it is also an important component of the growth of knowledge. Structural failure, not success, improves the safety of future generations of a design. A failed structure is a counterexample to the engineer's hypothesis and shows what cannot be done; a structure that stands without incident often conceals whatever lessons it might hold for the next generation of engineers. For these reasons, Petroski argues that design literature needs to incorporate descriptions of failures.

DESIGN AS INTELLECTUAL WORK

This entry is based on the premise that the literature of design from other disciplines is relevant to the library and information sciences. Words frequently used in descriptions of a "designerly way of thinking" are creativity, fluidity, rationality, intuition, emotion, reflection, confidence, and taste. While these characteristics certainly apply in other kinds of work as well, in the practice of

design they take on a unique character in relation to pervasive uncertainty.

Before discussing the elements of design thinking that are thought to be common across boundaries, it may be useful to consider what does not cross the boundaries. In Schon's 1983 study^[38] of six professions, he identified four areas where each had unique elements: (1) the media, languages, and repertoires [of action] that practitioners use to describe reality and conduct experiments; (2) the appreciative systems [values] they bring to problem setting, to the evaluation of inquiry, and to reflective conversation; (3) the overarching theories by which they make sense of phenomena; and (4) the role frames within which they set their tasks. These more stable elements of the situation give the practitioner relatively solid references from which she can work to address the unknowns of the design; they provide a base for reflection in action. It is in the constantly evolving confrontation with uncertainty, ironically, that designers have most in common.

Creativity has been described in this entry as being the necessary response to conditions of uncertainty. It is required in the initial work of setting a problem out of a fluid problem space. And, as Lave^[39] says, one does not have a problem without a sense of a resolution space as well. David Kelley, founder of the widely recognized design firm IDEO, emphasizes that successful design depends on being open to multiple possibilities and being ready "to take risks in a creative leap into possibilities that are not yet defined and whose consequences are not yet visible."^[40]

Wagner^[24] similarly describes an architect's ability to perceive "the novel within the familiar, to discover relations between seemingly incongruent objects and notions, to relate the unrelatable." She describes designing as an informal, fluent process, simultaneously focusing on floating concepts, preliminary specifications, and contradiction and constraints. The process she describes is closely related to Schon's^[4] description of the path from initial idea to final design as unpredictable, emerging out of a conversation in which the materials "talk back" in response to each decision made by the designer.

This fluidity in thinking, closely related to creativity, is important in the intellectual work in design. A designer must be able to keep seeing a problem from new perspectives, avoiding filters that make everything conform to that filter. Designers must first look as broadly as they can at the universe of possible solutions; then they can feel more comfortable narrowing. It is important that hypotheses be formulated, tested, discarded, and revised; understanding of the problem, the tools, and the materials of the situation changes as the three interact.

It is often stressed that designers need to be able to live with pervasive uncertainty. "The typical design situation requires doing something that you don't yet know how to do."^[41] In addition, it is never possible to be certain that one has done it in the best possible way; there may always

be a new, better solution that one stopped just before reaching.

Rationality was the central concern of designers early in this century, and is certainly not dismissed by contemporary theorists. Intuition is fed by experience. Solid disciplinary knowledge is a prerequisite to meaningful creativity. If one does not understand the formal properties of the tools and materials, then there is no basis for the deeper insights that can come from failures. *The Structural Engineer*,^[42] the official journal of the British Institution of Structural Engineers, defines structural engineering as "the science and art of designing and making. ..." Petroski argues that design is first articulated by the engineer as artist, and then analyzed by the engineer as scientist.

Intuition is another dimension of the work of design. "Creative leaps" can be based on intuition about what will work, the sense of a resolution space, as can be the hypotheses tested in building models.

Emotion in design takes various forms. Designers have been compared to athletes; they want to design the best thing they possibly can. There are no professional rewards for copying existing designs, although that work is likely to solve problems safely. Kelley,^[43] says "the designer has a passion for doing something that fits somebody's needs, but that is not just a simple fix. The designer has a dream that goes beyond what exists, rather than fixing what exists. ... there is a satisfaction in addressing problems at a deep level." Surprise is a frequent emotion in good design, because of the indeterminacy of the work. At times commitment to an organization or a social goal is a strong motivator, and an additional source of satisfaction in success. A sense of play is emphasized in some design organizations, because it opens up new approaches which might not be considered otherwise. Design teams often keep an assortment of gadgets around to stimulate play and exploration that can lead to innovative work.^[44]

Taking a risk in design means making a decision to create something that is not proven to be what is needed to solve that problem. Kelley asserts that even the most flexible people are uncomfortable with this kind of risk taking, but learn to live with that discomfort. Emotion, if it takes the form of commitments to particular ways of doing things or avoidance of uncertainty, will constrict design work.

Design requires confidence, the ability to make a creative leap and follow a path which doesn't yet exist. According to Kelley, a good designer creates beyond what the problem calls for, to create a solution that fits in a deeper situational or social sense. Kelley sees the designer's approach to a problem situation as dramatically different from that of an engineer, whose solution is based on mathematics and certainty. "A good problem in design is one for which you aren't sure that there is a right answer."^[45]

Related to confidence is a designer's ability to tell when she's got something that's good, an inner gyroscope that allows her to evaluate her own work.

DESIGN RESEARCH

"Design research" is a term used in some fields for design that is undertaken for the explicit purpose of extending the knowledge base; it may be instantiated to solve a particular problem, or its purpose may be proof of concept, demonstrating that a particular solution is possible. Design is considered research rather than practice on the basis of its greater novelty and difficulty, its significance to a research community, there being a serious question about how to solve it and its being "rigorously defined, formally represented, coherent, and internally consistent."^[2] Hevner et al.^[2] broaden the requirement of significance in information systems work to include social analysis of the design in use, with information provided to managers about the best deployment of the artifact. Design research takes place primarily in corporate laboratories and universities, thus having some characteristic differences from design in the field, notably in problem definition and constraints.

In a corporation, design is a strategic competency;^[46] a good problem is one that will contribute to the trajectory of the company's competitive strength. Teece et al.^[47] argue that a firm's previous investments and the repertoire of routines it has established create its current position, and that the current position is the primary constraint determining the paths available ahead. Learning tends to be local, and opportunities in the neighborhood of a firm's prior research are the paths most available. A company's history thus shapes and constrains its problem definition, and even what is recognized as a problem. A research culture develops that defines the optimum amount of novelty, and the levels of difficulty and uncertainty that are acceptable. Research cultures change over time, as may be seen in the fact that since the 1990s, U.S. R&D programs have shortened their focus, de-emphasizing basic research, and companies have favored design problems with a clear line-of-sight to market.^[48]

In universities, disciplinary value systems dominate, shaping and sometimes overriding the goals of university administrations.^[49] Disciplinary value systems emphasize theory and original contributions to knowledge. The significance of research questions is defined by the discipline, embodied in scholarly journals' decisions about what is important enough to publish and what is not. Problem setting is always influenced by the tension between the need to produce new knowledge and the risks of working outside the established disciplinary boundaries.^[20,50] This tension is passed on by dissertation committees and tenure committees taking seriously their responsibility to socialize new members into the academic culture. Weedman,^[49]

in a study of a design research project, found that students and junior faculty were advised away from problems that lay outside disciplinary boundaries.

The national emphasis on direct applicability has affected university design research as well as corporate laboratories. In the 1980s and 1990s, federal funding for basic research decreased, generating attempts to make "theory" more "relevant" in several disciplines. Addressing computer science and engineering (CS&E) in 1992, for instance, the National Research Council called for these disciplines to focus on "substantive research problems in the context of their application in and relevance to other domains."^[51] They urged collaborative projects between researchers in CS&E and client disciplines who would be the users of the designed artifact. Recognizing the tension between the scholarly requirements of a discipline and the practical requirements of users, the NRC anticipated that CS&E could "thus be framed simultaneously as a discipline with its own deep intellectual traditions, as well as one that is applicable to other problem domains. CS&E [could] thus be an engine of progress and conceptual change in these other domains, even as they contribute[d] to the identification of new areas of [scholarly] inquiry" (p. 65). This approach turned out to be fraught with problems, as the incentive structures of both the design and the client disciplines worked against mutual problem definition.^[20,49]

A special section in *MIS Quarterly* in 1999^[52] made similar recommendations, framing the tension as rigor vs. relevance. Overemphasis on rigor was seen as posing a danger of irrelevance, because of the need to formalize the problem, removing considerable sources of uncertainty present in design in the field. Several authors argued for the importance of combining relevance and rigor: rigor provided by building on the research knowledge base and relevance provided by selecting problems that would lead to the design of artifacts for specific situations. Benbasat and Zmud^[53] asserted a symbiotic relationship between researchers and information systems practitioners: "Theories and models are judged on their predictive power for guiding practitioners, the quality of theories are enhanced by testing and revising them with data from the world of practice, and the cues and insights offered by practitioners are assessed through rigorous examination across a variety of contexts." They note that much of the perceived irrelevance of research to the field may be the result of the way it is reported; to be useful, research reports must be shaped for the needs and concerns and rhetorical styles of the different audiences. Hevner et al.^[2] define design science problems as dual problems requiring dual reports, one scholarly for other researchers and one for business managers who need to understand the role of information systems and specific features in achieving their company's goals. The research problem is defined as a problem in the field as well as a disciplinary problem.

Not all researchers perceive an opposition between relevance and rigor; Lyytinen,^[54] for instance, wrote that many authors seemed to believe that there is a law that reads “rigor will always replace relevance if there are no powers to stop it.” He argued for more reflectiveness about the concept of relevance and the assumption made by many that relevance means rigor watered down or simplified, something that can be read and learned in an afternoon. He notes that relevance does not preclude research reports from being difficult, theoretical, and challenging, thus resolving the double vision of dual problem definitions.

There are also constraints unique to design research. Researchers in professional schools are often expected to fulfill obligations to the field for which they are preparing their students at the same time that they adhere to norms of the academic discipline. Practitioners or the clients for design projects often believe that design done as research is not relevant to actual needs in the field. Research may be perceived as too far in advance of practice to be applicable in “the real world” or as lagging behind practice, starting from scratch to develop proof of concept for something that has been done in the field (perhaps on a smaller scale) already. Formalized, mess-free designs often cannot be instantiated in actual work sites, or the cutting-edge theoretical problems that researchers need to address may not be perceived as problems in the field. An inability to satisfy both sets of constraints can lead to great frustration in a design research project.^[49]

Another set of constraints unique to design research is the relationship between standards and novelty. Design research requires novelty, yet a design must be standards compliant if it is to be built and used. Codified knowledge represents virtuoso performances within established boundaries; formal standards such as those issued by the American National Standards Institute cannot anticipate all future design situations. Bucciarelli^[55] writes that “a code is a historical statement based on experience and testing, but mostly on experience. Design is design of the new and the untried, the unexperienced, the ahistorical.” The constraints of university research require that design be novel, and therefore often outside established boundaries. Yet if it is to be used, a system needs to conform to the constraints created by technical standards. Goals to design an interesting research system that is also standards compliant must meet sometimes antithetical constraints.

DESIGN SCIENCE IN THE LIBRARY AND INFORMATION SCIENCES

Two examples suggest ways in which design science might be incorporated into the library and information sciences. One is a study of designers of controlled vocabularies for local use in image collections; the other is an ongoing design research project using probabilistic information retrieval systems.

Design Science: Local Vocabularies for Image Collections

In LIS, design work related to knowledge organization is carried out simultaneously at multiple levels—in the devising of national standards for design such as the National Information Standards Organization (NISO) *Guidelines for the Construction, Format, and Management of Monolingual Thesauri*, in the maintenance of major vocabularies such as the Library of Congress’ *Thesaurus for Graphic Materials*, in the design of vocabularies intended to be diffused widely such as the *Art & Architecture Thesaurus*, and at the local level in the creation of descriptors or classification systems for individual collections of materials.

This study^[56] consisted of a survey of individuals who had created or worked with locally designed vocabularies for image collections, and interviews with the respondents who had participated in the creation of a vocabulary. In the interviews, open-ended questions were asked in order to elicit description of the process—the work—of vocabulary design. Transcripts of the interviews were then coded and analyzed to ascertain whether or not concepts taken from design literature such as those discussed in this entry were applicable to design in this area of library and information science. The 2004 report was based on the first six interviews to be conducted. The sites included a collection of urban photographs, a historical site containing many objects as well as photographs, a collection of illustrated medieval manuscripts, a collection of magazine photographs illustrating mid-twentieth century culture, the photograph collection of a medical research center, and the visual resources collection of a university art department.

Uncertainty was pervasive in the work of vocabulary design. The uncertainty of language is said to plague information retrieval, with its synonyms, homonyms, nuances, and context-dependent meanings; Morville,^[57] for instance, calls language “the questionable foundation upon which information retrieval is built.” However, it was not language that caused the most uncertainty for the respondents. In information retrieval, language creates relationships between documents—identifying shared attributes that will aggregate some images and discriminate them from others. It was the relationships themselves about which the vocabulary designers rarely felt comfortable. The establishment of these relationships, though informed by the discipline or setting of the collection and the anticipated needs of users of the collection, was still, ultimately, a creative act by the designer, for which there was no ultimate test of correctness. The most uncertainty of all was felt about the breadth and specificity of the relationships—how broadly the aggregating attribute should be defined, whether the images it would bring together would constitute the most useful grouping, whether the entities that could be brought into that

relationship should be. The designers reported that it was these relationships, not the words used to express them, that were the source of the worst uncertainty in their vocabulary design.

Conversations with the materials of design did occur. Most frequently they took the form of arranging and rearranging terms to see the relationships which resulted. Adding a new image to those previously included in a category often changed the earlier the relationship, requiring different configurations to accommodate new possibilities. Even using terms that were well established in the domain did not solve the problem of which relationships to create and which to leave invisible; an established term would create one relationship, but then some items would need to be disaggregated because they differed in some critical dimension. Designers often considered the effects of using one term or set of terms to express relationships, then changed the terms and relationships to see what the result was. Creation of a new term could affect the scope of the first. "You have to be willing to mess with things." One respondent said that he designed vocabularies in the same way that he baked bread, through experimentation—"I try things and then respond in accordance with what's happening."

There are, of course, various constraints on the work of vocabulary design. The existence of standardized structures is one constraint; one designer compared a sense of structure to a painter's understanding of oil and canvas, and said that if one didn't fully understand the nature of structure, the designer could be "misled by content." Time and money were common constraints that shaped the final vocabulary. The size of one of the older vocabularies was determined by the computer available for use and the size of its memory. In an art history library, the decision about whether a vocabulary should capture literal objects in an image or their symbolic meaning was determined by the fact that the actual indexing would be done by students who had taken not more than one art history class. User warrant, literary warrant, and the warrant of standard vocabularies such as the *Art & Architecture Thesaurus* are other forms of constraint that influence design work.

Problem setting was influenced by these constraints and other factors. In no case was the problem that gave rise to the creation of a vocabulary simply the need to provide intellectual access to the image collection, even when that was given as the initial problem statement. In the case of the urban photographs, providing intellectual access was first described as "trimming down" the descriptive terms assigned by the photojournalists, despite their unsuitability for information retrieval; this turned out to mean bringing consistency to the terms while preserving them as part of the intellectual whole of the photographs and their descriptions, to be followed by the design of an independent vocabulary for information retrieval when the collection was merged with others. In the case of the illustrated manuscripts, the general goal of providing

intellectual access turned out at its core to mean relating the illustrations to the part of the story they depicted, so that different versions of the same work could be compared by a professor and his graduate students whose research centered on this one work. The vocabulary would be useful for others doing the same kind of research, but not for individuals studying the work in different ways. An initial problem description of designing a vocabulary in one situation turned into "find something you can do NOW," bypassing the content management vocabulary for the Web site which had run more than a year beyond its deadline. For the historic site, the problem was defined both as providing computer access so that users could find things on their own, and as bringing together the materials that were all related to the same story. Doing good in the world was another problem definition that emerged well into an interview.

The designers interviewed were employed as librarians, metadata specialists, curators, or in other positions; vocabulary design was only one of many responsibilities. All said that they saw the design work as different in nature from other parts of their jobs. They saw it as requiring more creativity, making something that hadn't existed before. Some of the creativity was in the act of putting oneself in the minds who would be using the images. One designer captured the role of constraint in novelty when he commented that "when you understand your audience you can be creative." The importance of seeing things (in images) in relation to one another was strongly emphasized. They cited an intuitive dimension, a sense of how things should go together and of when a relationship wasn't right. Emotion was also present in the work, sometimes unexpectedly, as in the discovery of slave records in the historical site. There was an emotional connection with design work that took the form of curiosity about "how things could be brought together into a structure." Enjoyment of "pulling things apart and putting them back together" was important to one of the designers. Emotion was also cited as a negative factor; one's response to images could get in the way of subject analysis.

Themes taken from the study of design in other professions provided a useful frame in this study for exploring design practice in the library and information sciences. Discussions of uncertainty, problem setting, the conversation with materials, and other concepts provided a different set of insights into vocabulary design than is gained from other research approaches.

Design research: Cheshire

The development of the Cheshire information retrieval system, begun in 1990, is an ongoing design research project. Cheshire was developed by Ray Larson at the University of California, Berkeley. I interviewed him in 2007, again with the goal of determining whether concepts from the design literature of other disciplines would be

echoed in descriptions of design work in the library and information sciences. The initial question was very broad; “tell me about the history of Cheshire—how it started, how it changed and why, why you made the decisions you did.” The questions that followed focused on the actual work performed by Larson; what kinds of things he did, how he made decisions, and so on.

The history of Cheshire over 17 years illustrates many ways that uncertainty, problem setting, conversations with materials, constraints, the role of tools, and failure play out in design research in LIS. In a large project of long duration, none of these factors come into play only once. They interweave in various ways throughout the life of the project.

Problem setting is required at many stages of design research—in the development of Cheshire, the initial problem was redefined to take advantage of opportunities, in response to the tools available, to accommodate the unexpected, and to address subparts of the problem more specifically.

Larson began defining the problem during his dissertation work, a computer performance evaluation of the UC systemwide library catalog, when one of his findings was that users experienced subject searching as very difficult, often learning to avoid it as much as possible. At this time, the commercial search engines were entirely Boolean. Ranked retrieval appeared as the alternative to explore; William Cooper, with whom Larson had studied, argued that ranked retrieval was the optimum way to do subject searches, and W. E. Maron, with whom Larson had also studied, argued that probability theory provided the best foundation for ranked retrieval. There were two major theoretical approaches for providing relevance ranking of results, neither of which had been instantiated in full working systems because of their computational requirements. The first was that of W. E. Maron and J. L. Kuhns, who had published “On relevance, probabilistic indexing, and information retrieval” in *Journal of the ACM* in 1960,^[58] and the second was the vector space model, Gerard Salton’s SMART system.^[59] Although Larson initially framed the problem as a need for probabilistic retrieval for subject searching, none of the computers available could carry out the computationally intense procedures; the early experiments leading to Cheshire, then, were carried out with the vector space model.

Because of his dissertation work and the availability of the library’s records, Larson began with the MARC (Machine Readable Cataloging) format, but in a graduate class that gave his students the opportunity to build an IR system from the ground up, Larson and the students realized that the MARC format imposed too many constraints and that a more generalized markup language was needed. This led, after investigation, to a new subproblem, conversion to SGML (Standard Generalized Markup Language), and the system designed in the class became the first Cheshire.

The problem definition shifted again—back to probability theory as the design model—when Larson joined a multimillion dollar research project on data management in the earth sciences that made state-of-the-art computers available to the investigators. Cheshire then became Cheshire II.

The chance to build probability algorithms into a working system exposed a set of unanticipated problems—the formal results differed from the way that code actually behaved. Problem definition shifted to address differences between the model and the instantiation. Then the problem definition changed again and became how to incorporate the relevance feedback on which the probability model depends. The solution was to employ logistic regression on samples of documents for which human relevance judgments had been made, to determine which of their characteristics would predict that someone would judge the document to be relevant. The statistics from this sample are then used as the basis for the relevance ranking in the rest of the database.

Cheshire3, developed together with investigators in England, will be the next generation. A part of the problem set for Cheshire3 is to have it search multiple collections and determine the best one in which to carry out a given query; this problem definition is made possible by the fact that many of England’s archival databases use Cheshire II search engines, allowing them to be used as test sites.

Larson describes his work process as starting with a vision of what he would like to have the system be able to do, and then discovering “all the little details” that are needed to make it happen. Conversations with materials often led to increasingly complex and convoluted code, until suddenly Larson would see a different way of solving the particular subproblem that would be more direct. The module would then be rebuilt. The process of creating Cheshire II contained many of these long conversations and sudden insights.

Larson described the path between “I’d like it to do this” and the point where the search engine *does* “this” as “a combination of pondering, visualization, imagining, and ‘how could one...?’” The questions are “what data do I need to give it so it can do this? How do I get that data and how would I need to process it in order to make the outcomes be what I want them to be?”

Fluidity is the greatest when something is partially working. At that point there is design room for experimentation. Things can be tried to see what happens, then dropped or modified. The history of the conversations with materials can be traced in what Larson refers to as an “archeology of code.” Some unused appendixes couldn’t be removed because of shared variables, so they were left. Other obsolete pieces were left because it takes longer to remove code than it does to write it in the first place. So working code exists in layers over, and intertwined with, old code. A designer works down through that archeology

when the addition of a new feature involves rewriting a dozen or more modules, because making one sort of change at the top level often requires that you change other things that interact with it layers down. Having written the largest share of code himself, Larson speaks of his intimate relationship with it, knowing not just where everything is but how its particular form is the result of design paths begun and abandoned, unanticipated modifications and their unanticipated results on existing code, fixes, and then fixes to fixes.

The material with which the designer conducts a conversation is not, Larson stressed, the code itself. The conversation occurs when he runs the program and looks at the data that results, and the “back talk” is the appearance of needless duplications or errors in the way that the data comes out. The designer isn’t having a conversation with the underlying algorithms per se; but he has to find where in the code the problem is located to try to fix it. Finding out if he has indeed fixed it requires another conversation.

Intuition and insights are part of the intellectual work of this kind of design. Sudden insights sometimes occur after a fruitless struggle with a problem that seems impossibly difficult, or doable but not in any reasonable amount of time; it’s not unusual to wake up in the middle of the night with “oh!—wait a minute, wait a minute!—I can do it *that way!*”

As other designers have described fluidity of thinking and the importance of unexpected juxtapositions, Larson has found that when a problem or approach seems insoluble, it’s instructive to “turn it on its side or turn it on its head or turn it around completely, turn it backwards, and see what happens.” And very often the different perspective makes visible (or discoverable) a better way of doing it.

An example is the design problem of including functionality for geographic retrieval in Cheshire3. Study of searchers shows that they scan through all the possible items until they find the one that would serve their purposes, which would be impossible in a large-scale system. R-trees in computer science are used for searching regions, but would have been “horrendously” complex to implement in the system. Larson describes spending a great deal of work on how to incorporate R-trees before asking what *else* could be done. Software developed within another Berkeley research project, Berkeley DB, gives access to the underlying index structure of a database. The techniques of Berkeley DB plus some middle-of-the-night inspirations led to a method that will in effect create R-trees but with the technique of creative scanning of the indexes. This turned out to be a solution that works accurately and very quickly.

Larson describes design as a cognitive process, with no emotional input except a desire to avoid approaches that have failed to work in the past. Emotions do accompany the cognitive process, however. Negative emotions are most often evoked not by the problem itself, but by

technical limitations or some other external factor. The frustration is not a productive part of the design process; rather, it’s a sign that it’s time to do something else for awhile. Positive emotions are feelings of accomplishment evoked by the sudden insights into solutions, the satisfaction of something working the way that it was expected to, and the elation that follows a middle-of-the-night insight, when “you can’t wait to get up and go in to try it out and see if it works.”

Standards are constraints that both enable and limit design work. The value of working with standards is that it’s possible to build for the existing infrastructure. Because of its use of XML, Cheshire can search any database that has an XML structure. Use of a standard may permit unexpected novel results as well. The Z39.50 protocol is an information retrieval standard used to extract data from different collections and build an index of the combined elements; any database that supports Z39.50 for querying or SRW (Search/Retrieve Webservice) and SRU (Search/Retrieve via URL) protocols can be harvested. When Z39.50 was built, it included common operators such as the “equal to” relationship, “greater than” or “less than,” truncation, and so on. One of the operators was named “relevance.” Some investigation revealed that no one had used that operator anywhere. What it does is direct the server to do relevance matching. This obscure operator allows Cheshire to search any server built on its model and direct it to rank the results for relevance.

Standards also provide the basis for the status quo; and as knowledge progresses, it diverges from the status quo. Forward-looking standards cannot anticipate all directions of development. Thus there is always a tension between infrastructure and change. Design research, because of its inherent novelty, puts pressure, small or large, on standards. The result in the short term is a proliferation of work-arounds, such as ways to bypass the preset record formats established by servers or by the Z39.50 protocols and request other formats. In the long term, standards change.

Problem setting is often affected by factors external to the project itself. The initial ability to do probabilistic retrieval, for instance, came from funding for a project focused on technology for global change research. Sometimes it comes from another interest of a researcher that can be blended into the design project; data mining capabilities were built into Cheshire3 as a result of one of the researchers’ interests in that area. Development of the UTF-8 encoding scheme for Unicode made it possible create cross-language retrieval. That led to the need for various tools, usually open source, to be incorporated, for example, a snowball stemmer that can be given a training data set that configures it for a particular language and from it create a stemmer for that language. Cheshire now has stemmers for all major European languages.

Problem setting in a university, as discussed above, has to respond to the norm of knowledge generation. When

ranked retrieval systems existed only as algorithms in the 1960s, Gerard Salton framed the field of information retrieval as an experimental science. The problem definition of Cheshire, Cheshire II, and Cheshire3 as practical application of theory in production environments resulted in both relevance and rigor as defined by the discipline,^[2] in both socially useful artifacts and articles reporting the theory and experimental research, comparing the base algorithms to other well-known information retrieval algorithms in terms of the standard measures of precision and recall.

This long-term design research project, then, does illustrate a “designerly way of knowing” in common with other forms of design. While primarily cognitive, there are elements of creativity, inspiration, and emotion. The conversation with materials plays an important role in the final form of the artifact, as does response to the fertile mix of challenges and constraints.

CONCLUSION

Although design is an important part of professional and research practice in the library and information sciences, it is at present undertheorized. Schools of LIS teach Web design, thesaurus design, management, public services, system analysis, interface design, XML, and other classes that have a strong design component. Our social science traditions provide strengths in understanding the use of systems, their integration into work life, and how users evaluate results; these traditions could usefully be expanded to study design as professional practice.

There are two potential benefits to studying our own design. One is that it may give rise to increased knowledge of and thereby improvement of design practice. Boland and Collopy^[32] write that the awareness of one’s own profession’s design practices enables discussion across professional boundaries, which can lead to new insights and “design attitude.” The other is the value of knowing for its own sake; the design that we do is important work, and understanding it is interesting. The review provided here of the “designerly way of knowing” in the information sciences indicates that there is a great deal of interest that could be done.

Dewey Decimal Classification (DDC)

Joan S. Mitchell

Diane Vizine-Goetz

OCLC Online Computer Library Center, Inc., Dublin, Ohio, U.S.A.

Abstract

This entry discusses the Dewey Decimal Classification's value proposition as a general knowledge organization system in terms of basic design, history, ongoing development, translations, mappings, applications, and research. The authors conclude with prospects for use of the DDC inside and outside of libraries.

INTRODUCTION

The Dewey Decimal Classification (DDC)^[1] system is a general knowledge organization system that is continuously revised to keep pace with knowledge. The DDC is used around the world in 138 countries; over 60 of these countries also use Dewey to organize their national bibliographies. Over the lifetime of the system, the DDC has been translated into more than 30 languages.

The system has value because of its well-defined categories, well-developed hierarchies, rich network of relationships among topics, worldwide use, and language-independent representation of concepts. The existence of interoperable translations, mappings to other subject schemes, and the large amount of categorized content already associated with the system also contribute to Dewey's value proposition.

BASIC DESIGN

Structure and Notation

The DDC structures knowledge by disciplines or fields of study in a general-to-specific arrangement in well-developed hierarchies. At the top level, the DDC includes 10 main classes:

000	Computer science, information and general works
100	Philosophy and psychology
200	Religion
300	Social sciences
400	Language
500	Science
600	Technology
700	Arts and recreation
800	Literature
900	History and geography

Each main class is divided into 10 divisions, and each division is divided into 10 sections (some numbers in the divisions and sections have not been used—these are marked as “Unassigned”):

500	Science
510	Mathematics
510	Mathematics
511	General principles of mathematics
512	Algebra
513	Arithmetic
514	Topology
515	Analysis
516	Geometry
517	[Unassigned]
518	Numerical analysis
519	Probabilities and applied mathematics
520	Astronomy
530	Physics
540	Chemistry
550	Earth sciences and geology
560	Fossils and prehistoric life
570	Life sciences; biology
580	Plants (botany)
590	Animals (zoology)

The top-levels of the DDC—the main classes, divisions, and sections—are known collectively as the “DDC Summaries.”

Arabic numerals treated like decimal fractions are used to represent each class in the DDC. In other words, main class 500 Science is really .5 Science. The main class, divisions, and sections are usually represented as three digits (extra zeros are added as needed). A decimal point (a punctuation device without mathematical significance) follows the third digit in a DDC number, after which division of the class continues by specific enumeration and/or notational synthesis. For example, 006 Special computer methods is divided into six subclasses: 006.3 Artificial intelligence, 006.4 Computer pattern recognition,

006.5 Digital audio, 006.6 Computer graphics, 006.7 Multimedia systems, and 006.8 Virtual reality. All but the last are further subdivided. In addition, each of these classes (including the last) can be further extended by general notational synthesis rules as well as instructions in specific classes.

Classes 000–999 are known collectively as “the schedules”; there are also six auxiliary tables (Tables 1 through 6) that support notational synthesis:

Table 1	Standard subdivisions
Table 1	Standard subdivisions
Table 2	Geographic areas, historical periods, persons
Table 3	Subdivisions for the arts, for individual literatures, for specific literary forms
Table 4	Subdivisions of individual languages and language families
Table 5	Ethnic and national groups
Table 6	Languages

Notation in tables is represented in the print edition with an em dash followed by the number, e.g., —624 Sudan is the Table 2 number for the country of Sudan. In the Relative Index in the print edition, and throughout the current Web version, the same number is represented by T2—624. The prefix for the table number and the em dash are removed when the notation is appended to another number (see the section “Notational Synthesis”).

The schedules and tables also include some numbers enclosed in square brackets and parentheses. Numbers in square brackets are not in current use. Numbers in parentheses are optional numbers—alternate notation for a concept. Optional numbers are provided to give emphasis to a topic not given preferred treatment in the standard notation.^[2] For example, Library and Archives Canada routinely prefaces the notation for American literature in English and French literature with “C” to represent Canadian literature, e.g., C813.6 is the optional number for 21st century Canadian fiction in English; 813.6 is the standard number for the same concept.

Accompanying the schedules and tables are the Manual and the Relative Index. The Manual provides extended discussions on choices among related numbers, and on classification in complicated areas of the tables and schedules. The Manual was first published in 1982 as a supplement to DDC 19;^[3] it was fully integrated into the system with the publication of DDC 20.^[4]

The DDC is indexed by a unique tool known as the “Relative Index.” The index is so named because it shows the relationship between subjects and the disciplines (or in some cases, the various aspects within disciplines) in which they appear. For example, the Relative Index entries for Garlic are as follows:

Garlic	641.3526
Garlic—botany	584.33
Garlic—cooking	641.6526
Garlic—food	641.3526
Garlic—garden crop	635.26
Garlic—pharmacology	615.32433

Within 641 food and drink, garlic appears in food (641.3526), and cooking (641.6526). Garlic also appears in botany (584); as a garden crop in agriculture (635.26); and in a subfield of medicine, pharmacology (615.32433). The interdisciplinary number for garlic is the one that appears opposite the unsubdivided entry for garlic (641.3526).

The Relative Index has been a feature of the DDC since the first edition of the system, and is considered one of Melvil Dewey’s unique contributions. Miksa^[5] traces the history of the Relative Index through the 22 full editions of the DDC with special attention to its nature as a conceptual indexing system, the conceptual contexts provided by Relative Index, and its treatment of concepts resident in internal tables. Green^[6] investigates the explicit and implicit relationships between Relative Index terms and topics in the schedules and tables.

Classes, Hierarchies, and Relationships

Each class in the DDC is defined by its position in a hierarchy, notes within the class, and a rich network of relationships with other classes. Relationships may be explicitly stated within the class itself, within other classes, and inherited through hierarchical relationships.

Entries in the schedules and tables have two main components—a DDC number and a heading (caption) describing the number. The entry may also contain notes that further describe the class, provide instruction for notational synthesis, or define its relationships with other classes.

796.932 Cross-country skiing
Including biathlon
Class here Nordic combination, Nordic skiing
For jumping, see 796.933

Hierarchy in the DDC is expressed through structure and notation. The DDC organizes knowledge first by discipline and then by subject in a hierarchical structure in which topics progress from the general to the specific. Each of the classes subordinate to the 10 main classes needs to be considered in terms of the hierarchy. Notes with “hierarchical force” regarding the nature of a class at any point in the hierarchy also apply to subordinate classes and to referenced classes.

The hierarchy is largely expressed through the notation. For a class within a given hierarchy, the next broader topic

will generally be represented by a number one digit shorter, and subordinate topics will generally be one digit longer. Coordinate topics are usually represented by the same number of digits. For example, here are several specific ice and snow sports shown in the context of their complete hierarchy.

700	Arts and recreation
790	Recreational and performing arts
796	Athletic and outdoor sports and games
796.9	Ice and snow sports
796.91	Ice skating
796.92	Snowshoeing
796.93	Skiing and snowboarding

The classes 796.91, 796.92, and 796.93 are coordinate classes—they are directly subordinate to class 796.9 Ice and snow sports, which in turn is subordinate to section 796 Athletic and outdoor sports and games. Section 796 is part of division 790 Recreational and performing arts, which is part of main class 700 Arts and recreation.

General Rules for Classifying with the DDC

The general rules for classifying with Dewey are set forth in the introduction to the DDC.^[7] Additional instructions are found in the beginning of Tables 1 through 6 (in the electronic version, the instructions can be found in the “0” record associated with each table, e.g., T1—0), in individual schedule and table records, and in the Manual notes associated with selected entries.

Since Dewey was originally developed to order physical materials, the instructions are geared toward the selection of a single number to represent any document-like object. The rules for choice of a single number also facilitate sharing of Dewey numbers among users, e.g., through bibliographic cooperatives such as Online Computer Library Center’s (OCLC’s) WorldCat. In the electronic environment, additional full and partial numbers may be assigned for access (see the section “Applications and Research”).

The guiding principle is to classify a topic within its disciplinary context. For topics scattered across the DDC, an interdisciplinary number is often identified. Within a discipline, a comprehensive number might be identified if there are aspects of a topic further developed in the discipline. For example, holidays may be examined from the perspectives of customs, law, religion, etc. The numbers for holidays will vary from each of these perspectives, e.g., 394.26 (Holidays—customs), 344.091 (Holidays—law), and 203.6 (Holidays—religion). The class 394.26 is designated the interdisciplinary number for holidays. It is also the comprehensive number for holidays in customs—there is a substantial development for holidays under

394.26 for secular and religious holidays, plus provision in 394.25 for Carnival and Mardi Gras.

Notational Synthesis

The DDC schedules enumerate only a fraction of the possible numbers that can be used to represent concepts. Often, a number must be synthesized (built) to express a particular concept. Numbers can be synthesized using notation in Tables 1 through 6, notation from other parts of the schedules, or notation from add tables that appear in the schedules. Any number can be extended by notation from Table 1, known collectively as “standard subdivisions,” unless there are instructions to the contrary.

Number building from the Tables 2 through 6, other parts of the schedules, and add tables can only be initiated upon instruction.

Here are some examples of notational synthesis in Dewey:

<i>Journal of Topology</i>	514.05
(514 Topology + notation 05 Serial publications from Table 1)	
The Internet in Africa	004.678096
(004.678 Internet + notation 09 Geographic treatment from Table 1 + notation 6 Africa from Table 2)	
Medical journalism	070.44961
(070.449 Journalism in specific subjects + notation 61 from 610 Medicine and health [it is a convention in Dewey to drop the final zero after the decimal point])	
Elementary mathematics curricula	372.7043
(372.7 Elementary education in mathematics + notation 043 Curricula from the add table under 372.3–372.8 Elementary education in specific subjects)	

HISTORY

The DDC was conceived by Melvil Dewey in 1873 and first published in 1876.^[8] Dewey developed the system as an economical alternative to the practice of organizing books first in broad categories, then by a fixed location within each category representing a physical shelf location. There were no relationships built within the categories except for order of acquisition. Dewey decided to use decimal numbers to represent the subject of books—under his system, books would be numbered according to their subject content instead of physical location. The system gets its name from Dewey’s surname plus the decimal element in its design. Wiegand,^[9] Comaromi,^[10] and Miksa^[11] discuss the early history of the DDC and influences on Melvil Dewey in his development of the system; Comaromi and Miksa also discuss the development and

features of subsequent editions of the DDC through DDC 18 and DDC 21, respectively.

Editions

The system is published in full and abridged editions, and in electronic and print versions. The DDC databases associated with the full and abridged editions are also available to licensees as an XML data file.

DDC 22, the latest English-language full edition of the DDC, was published in print in 2003;^[12] Abridged Edition 14, an abridged version of the full edition, was published the following year.^[13] The current full edition database contains nearly 27,000 numbers enumerated in the schedules, plus more than 13,000 additional synthesized numbers in the index. There are over 9000 table numbers listed in Tables 1 through 6; an additional 600 synthesized table numbers are included in the index.^[14] As mentioned previously, additional notation beyond that explicitly provided in the schedules, tables, and index can be synthesized to reflect a particular aspect of a topic.

The abridged edition is a logical truncation of the notational and structural hierarchy of the corresponding full edition. It is much smaller than the full edition—in print, it is one volume instead of four, and is aimed at collections of 20,000 titles or less. It also contains fewer tables than the full edition—Tables 1 through 4 instead of Tables 1 through 6. There are still opportunities for notational synthesis, but they are more limited than the full edition provisions for number building. The current abridged edition database contains nearly 5000 numbers enumerated in the schedules, plus an additional 400 synthesized numbers in the index. There are over 500 table numbers listed in Tables 1 through 4, plus nine additional synthesized table numbers in the index.^[15]

Electronic Versions of the DDC

The conversion of DDC to electronic form began in 1979 with the use of a computer-based photocomposition system to produce DDC 19. Five years later in 1984, Forest Press commissioned Inforonics, Inc., to develop a database and online system to support the continuing development and publication of the DDC.^[16] The project and resulting system become known as the Editorial Support System, or ESS. John Finni, the chief programmer from Inforonics, and Peter Paulson, the executive director of Forest Press from 1985 to 1998, envisioned that DDC data would also be used in classifier-assistance tools and in end-user retrieval systems. In 1989, the ESS was used by the Dewey editorial team to produce DDC 20. Electronic Dewey was released by OCLC Forest Press 4 years later. Electronic Dewey marked the start of classifier access to machine-readable classification data. The software ran on a personal computer and provided access to

the schedules, tables, Relative Index, and Manual of DDC 20 on CD-ROM. For schedule numbers, Electronic Dewey also provided up to five frequently used Library of Congress subject headings (LCSH) and a sample bibliographic record for the most frequently occurring heading.

A new Microsoft Windows®-based version of the software, Dewey for Windows, was released in mid-1996 at the same time as the publication of DDC 21. Dewey for Windows was based on the DDC 21 database and included significant enhancements to the user interface.^[17] The Windows version included statistically mapped LCSH and selected LC SH editorially mapped to DDC numbers. Dewey for Windows was issued annually through 2001.

In June 2000, WebDewey, a Web-based version of DDC 21, was released by OCLC as part of the Cooperative Online Resources Catalog (CORC) system. The CORC project grew out of the work of OCLC researchers to develop automated tools for finding, harvesting, and classifying electronic resources. In 2002, WebDewey and Abridged WebDewey, the latter a Web-based version of Abridged 13, became available in the OCLC Connexion cataloging service. These services replaced Electronic Dewey and Dewey for Windows.

The latest full and abridged versions of the DDC are available in the Connexion service. WebDewey and Abridged WebDewey incorporate all changes to the print editions, plus additional index terms and built numbers, and many other enhancements.

WebDewey features^[18] include:

- Regular database updates incorporating the latest changes to the DDC (new developments, new built numbers, and additional electronic index terms).
- Updated mappings to DDC 22 from the OCLC publication, *People, Places & Things*.^[19]
- Thousands of LCSH that have been statistically mapped to Dewey numbers from records in WorldCat or intellectually mapped to Dewey numbers by the DDC editors.
- Thousands of Relative Index terms and built numbers not available in print.
- Links from mapped LCSH to the LCSH authority records.
- Selected mappings from Medical Subject Headings (MeSH).

Abridged WebDewey features^[20] include:

- All content from Abridged Edition 14, including regular updates.
- LCSH that have been intellectually mapped to Dewey numbers by DDC editors, including mappings from the OCLC publication, *Subject Headings for Children*.^[21]
- Links from mapped LCSH to the LCSH authority records.

- Mappings between abridged Dewey numbers and subject headings from H.W. Wilson's *Sears List of Subject Headings*.^[22]

One by-product of the development of the DDC Web-based versions was the generation of a suite of XML representations of DDC data. The XML representations are used by OCLC in products and services and distributed to translation partners, research partners, and other licensed users. The proprietary XML representations are scheduled to be replaced by ones based on the MARC 21 formats for Classification and Authority data. The conversion is being undertaken in conjunction with the development of a new version of the ESS. In the new ESS, the record format used for schedule, table, and Manual data will be based on an enhanced version of the MARC 21 Format for Classification Data. The record format used for Relative Index headings and for mapped headings from other vocabularies will be based on an enhanced version of the MARC 21 Format for Authority Data. The MARC 21 representations of the files will also be available in XML.

Emerging data models for representing knowledge organizations schemes, e.g., Simple Knowledge Organization System (SKOS), may provide new opportunities for publishing, linking, and sharing classification data on the Web. Panzer^[23,24] identifies several issues that must be addressed before the DDC can be transformed fully into a Web information resource, including the design of Uniform Resource Identifiers and modeling DDC in SKOS.

DEVELOPMENT

Since July 29, 1988, OCLC has owned all copyright rights in the DDC and funds the ongoing development of the system. The Dewey editorial office has been headquartered at the Library of Congress since 1923, and is physically located in the Dewey Section.^[25] Dewey numbers have been assigned to works cataloged by the Library of Congress since 1930; classifiers in the Dewey Section are the primary assigners of Dewey numbers at the Library of Congress. Having the editorial office in close proximity to a key user group assists the editors in detecting emerging topics and shifts in viewpoints and terminology.

The DDC is continuously developed and updated by an editor in chief and four assistant editors. The editors study the distribution of topics in WorldCat to determine literary warrant (the existence of a certain level of literature on a topic) for updates—they also monitor the subject literature, news feeds, and other information resources, plus consult with users.

All changes to the DDC are reviewed by the Decimal Classification Editorial Policy Committee (EPC), a

10-member international advisory board whose main function is to advise the DDC editors and OCLC on matters relating to changes, innovation, and the general development of the DDC. The committee is a joint committee of the American Library Association and OCLC and has been in continuous existence in its present form since the early 1950s. Current EPC members represent academic, national, public, school, and special libraries and come from Australia, Canada, South Africa, the United Kingdom, and the United States. In addition, current translation partners serve as corresponding members of EPC—they receive all draft proposals for comment at the same time as EPC members.

TRANSLATIONS

Over the life of the system, the DDC has been translated into over 30 languages. Translation activities and international use prior to acquisition of Forest Press by OCLC in 1988 are summarized in Downing and Yelland^[26] and Holley;^[27] later activities are discussed by Chan and Mitchell,^[28] Beall and Couture-Lafleur,^[29] Knutsen,^[30] Heiner-Freiling,^[31] and Beall.^[32] Since 1988, authorized translations of the full and abridged editions of the DDC have been published in the following languages: Arabic, French, German, Greek, Hebrew, Icelandic, Italian, Norwegian, Russian, Spanish, Turkish, and Vietnamese. MelvilClass, the German counterpart to WebDewey, is an up-to-date version of the German translation of DDC 22. Other Web versions are currently under study. Current versions of the top-level summaries of the DDC have been translated into Arabic, Chinese, Czech, French, German, Hebrew, Italian, Norwegian, Portuguese, Russian, Spanish, Swedish, and Vietnamese. A project is under way in South Africa to translate the DDC Summaries into the ten official languages of South Africa besides English.

OCLC enters into agreements with recognized bibliographic agencies around the world to produce localized representations of the DDC in which classes remain interoperable with the English-language edition on which the translation is based. Translations are localized with examples and terminology appropriate to the country/language group, and are often supplemented by interoperable expansions (e.g., a deeper representation of a geographic area than found in the English-language full edition).

The following example illustrates the principle of interoperable expansions. The German translation of Table 2 contains expansions for several areas; the expansion for—43551 Regierungsbezirk Köln is shown below. The English-language version of the development for —43551 Regierungsbezirk Köln is a logical abridgment of the German version. In the English-language version of Table 2, only the categories shown in bold are listed.

—43551	Regierungsbezirk Köln
—435511	Aachen
—435512	Kreise Aachen, Heinsberg, Düren, Euskirchen
—4355122	Kreis Aachen
—4355124	Kreis Heinsberg
—4355126	Kreis Düren
—4355128	Kreis Euskirchen
—435513	Rhein-Erft-Kreis
—435514	Köln
—435515	Leverkusen
—435516	Rheinisch-Bergischer-Kreis, Oberbergischer Kreis
—4355163	Rheinisch-Bergischer-Kreis
—4355167	Oberbergischer Kreis
—435518	Bonn
—435519	Rhein-Sieg-Kreis

Research projects are under way on models for mixed Norwegian-English and Swedish-English translations of the DDC,^[33] and on multilingual presentations of the DDC.^[34]

Translations enrich the terminological base of the DDC, and extend the specificity of the system in the form of interoperable expansions and additional synthesized numbers. Translations also spur additional categorized content being associated with the DDC.^[35] Translation partners bring a rich diversity of viewpoint to the DDC that often results in improvements to the English-language standard edition.^[36]

MAPPINGS

Mappings between Dewey and other knowledge organization systems enrich the vocabulary associated with DDC numbers, and permit the use of the DDC as a switching system. Current services plus a host of research projects make use of such mappings for a variety of applications.

The electronic versions of the DDC contain selected mappings between Dewey numbers and three standard subject headings lists—LCSH, MeSH, and H.W. Wilson's *Sears List of Subject Headings*. The last represents the longest continuous mapping between the DDC and a subject heading systems. Dewey numbers first appeared in the 4th Ed. of *Sears* in 1939.^[37] They were dropped in the 9th Ed. of *Sears*,^[38] reappeared again in the 11th Ed.,^[39] and have continued through the 19th Ed.^[40] The mappings between abridged Dewey numbers and *Sears* headings are created at H.W. Wilson under an agreement with OCLC, and are included in various products and services offered by OCLC and H.W. Wilson.

The Dewey editors have long consulted LCSH and MeSH as sources of terminology for the DDC; terminology from both systems is also mapped to the DDC. The OCLC publications *Subject Headings for Children and People, Places & Things* are lists of LC subject headings with corresponding DDC numbers. The publications function as tools for end users and catalogers and supply

vocabulary for the DDC database. Both include subject heading-DDC number pairs statistically derived from WorldCat. Vizine-Goetz^[41] describes the general processes used to map LCSH terminology, including statistical mapping. Ongoing access to LCSH mappings is through WebDewey services.

In 2008, the Dewey editors began a project to map DDC numbers to the BISAC (Book Industry Standards and Communications) subject headings.^[42] The project is part of OCLC's Next Generation Cataloging pilot, which captures publisher and vendor metadata and enhances it for the mutual benefit of library and publishing industry partners.^[43] The mappings are used to add Dewey numbers to publisher metadata records that contain BISAC codes, and BISAC subject headings to bibliographic records that contain DDC numbers.

Translation partners and other groups are also linking general terminology lists with the DDC.—> In the CrissCross project, headings from Schlagwortnormdatei (SWD), the German subject heading authority file, are being mapped to Dewey numbers (to date, 58,000 headings have been mapped).^[44] At the Italian National Central Library in Florence, work is under way to map Dewey numbers to Nuovo Soggettario, the Italian subject heading list.^[45,46] The Spanish translation of *Sears List of Subject Headings* also includes mapped Dewey numbers.^[47]

There are also concordances being developed between Dewey and other classification systems. The Library of Congress's Classification Web system includes statistical correlations among LCSH, Library of Congress Classification (LCC), and DDC based on the co-occurrence of the three in Library of Congress bibliographic records. The National Library of Sweden has developed a mapping between Sveriges Allmänna Biblioteksförning (SAB), the Swedish classification system, and the DDC as part of an exploration to consider a Swedish translation of the DDC.^[48]

Several concordances between the Universal Decimal Classification (UDC) and the DDC have been developed. For example, the Czech National Library has built a concordance between UDC and DDC for the purposes of collection assessment.^[49] McIlwaine and Mitchell are experimenting with a concordance between the Class 2 Religion in the UDC and 200 Religion in the DDC as a method of presenting a chronological/regional view of religion in the DDC similar to the updated one found in the UDC.^[50]

APPLICATIONS AND RESEARCH

The DDC is perhaps most familiar to users as the classification portion (Arabic numerals punctuated by a decimal point after the first three digits) of a call number used to label physical objects in libraries. The classification

portion of a call number is one manifestation of Dewey; the underlying DDC data and associated terminologies are used for a variety of applications beyond physical shelf location.

The first and most well-known research effort to incorporate DDC data into an end user retrieval system was the DDC Online Project led by Markey.^[51] Markey's team built an experimental online catalog, Dewey Online Catalog (DOC), that included data from the DDC schedules and Relative Index. The DOC system provided new subject searching capabilities not available in online catalogs, e.g., subject indexes enriched with terminology from the DDC schedules and Relative Index, and features to broaden or narrow searches using the DDC hierarchy. Other notable research projects that use DDC-based search strategies are the Renardus Service^[52] and the High Level Thesaurus (HILT) project.^[53]

The Renardus project developed a pilot Web-based service that enabled searching and browsing of subject gateway services from Denmark, Finland, Germany, the Netherlands, Sweden, and the United Kingdom. To enable browsing across the gateways, the local classification systems used in the gateways were mapped to a common classification system that could function as a switching language and browsing structure. The DDC was chosen as the common scheme. The project developed a mapping tool that allowed the participating gateways to specify the level of match between the local scheme and DDC.

Like Renardus, the HILT project is investigating and developing solutions for subject searching and browsing across multiple schemes and information environments. The DDC is used as a central spine to which collection descriptions are mapped. In the HILT II pilot service, user queries are matched to DDC captions, Relative Index terms, and mapped terminology; DDC caption hierarchies are displayed in search results to provide context for matched terms. When a user selects a result, the service returns a list of collections to search.

These systems are exceptional in their integration of DDC data into the search process. As Markey notes, "To this day, the only way in which most online catalog users experience classification online is through their OPACs shelflist browsing capability."^[54] Even so, the value of classification-based browsing has not gone unnoticed by users and developers of online catalogs. Many online catalog redesign projects include a requirement for a virtual shelf-browsing feature.

The approval of additional MARC 21 fields for DDC numbers in the bibliographic format may provide new opportunities for using DDC data in end-user and classifier systems. The 083 field (Additional DDC Number) can be used to code additional DDC numbers, including internal and external table numbers, for subject access.^[55] The 085 field (Synthesized Classification Number Components) traces the components of a synthesized number. Beall^[56] gives several examples of 083 and 085 fields and

discusses how the data can help libraries make full use of the DDC for retrieval.

Liu^[57] investigated the feasibility of decomposing DDC synthesized numbers in the 700s. He concludes that synthesized numbers can be decomposed automatically in all DDC classes and suggests that bibliographic records could be enhanced with additional indexing vocabulary based on the component parts of a number. Following Lui, Reiner^[58] is developing software to decompose DDC numbers assigned by the German National Library. The German National Library began assigning Dewey numbers to resources in its collection in 2004. The goal of this research is to develop software to automatically assign class numbers. It remains to be seen whether the MARC 085 field will stimulate new investigations into decomposition and automated number assignment.

The Library of Congress is employing a semi-automated approach for DDC number assignment. The "AutoDewey" software takes advantage of places where the LCC and DDC schedules for literature are similar enough to facilitate mapping between the two schemes. The software suggests DDC numbers based on the LCC number chosen by the cataloger for the work in hand.^[59] Where one-to-one mapping is possible, AutoDewey assigns DDC numbers automatically, based on the LCC number. When direct mapping is not possible, the cataloger must often choose a literary form (poetry, drama, and fiction); when the literary periods of LCC and DDC do not match, the cataloger must also choose a literary period. Almost 2400 DDC numbers were assigned in 2007 using AutoDewey, and 5105 numbers were assigned in 2008. The software was developed by the Library of Congress.

OCLC has taken a different approach with the beta service Classify.^[60] The service provides summaries of classification data (DDC, LCC, and NLM) for FRBR-based groups of WorldCat records. All summaries include the most frequently used number based on holdings and the most recently assigned class number based on OCLC record number; many also include Dewey edition information. The service supports the assignment of classification numbers for books, DVDs, CDs, and many other types of materials. Classification data is accessible through a user interface and a Web service.

Previously, in the research phase of the CORC project, OCLC introduced tools to help users assign DDC class numbers. The tools, now available in Connexion, consist of software that automatically generates DDC numbers for Web resources and a feature to apply authority control to Dewey numbers. Despite attempts to optimize the content of classification records for automated classification using the Scorpion software, fully automatic classification remains an unrealized goal.^[61,62]

The DDC is also being used for collection analysis and assessment. In the WorldCat Collection Analysis service, DDC numbers are mapped to the OCLC conspectus to enable libraries using multiple classification schemes to

analyze their collections as a whole.^[63] At the British Library, the DDC has been used in a pilot project to assess the library's collections in support of higher education in the United Kingdom.^[64]

CONCLUSION

A rich set of tools is critical for knowledge representation and access in an information environment in which information flows freely in all formats across national and linguistic boundaries. Knowledge organization systems such as the DDC have a yet-to-be-fully-exploited role to play in the current and future environment. The Dewey Decimal Classification—with its well-defined categories, well-developed hierarchies, rich network of relationships among topics, worldwide use, language-independent representation of concepts, interoperable translations, and mappings to other subject schemes, plus the large amount of categorized content already associated with the system—holds promise in a variety of applications beyond its familiar role as a shelf location device. The success of Dewey as a tool in current and future environments will depend on ubiquitous and convenient availability of the system in a variety of formats for experimentation and use, continued (direct and automatic) application of Dewey numbers to content, aggressive association of the system with a wide variety of terminological resources, and continuous updating and development of the system by the editorial team in partnership with the worldwide community of Dewey users.

Digital Content Licensing

Paul D. Callister

Kathleen Hall

Leon E. Bloch Law Library, University of Missouri-Kansas City School of Law, Kansas City, Missouri, U.S.A.

Abstract

Content licensing primarily concerns the licensing of property, and impacts legal rights under diverse bodies of local, national, foreign, and international law. Besides copyright law, content licensing may concern, depending upon the jurisdiction, the author or creator's "moral rights," "neighbor rights," lender's rights, defamation, privacy, publicity, pornography and obscenity, international trade, exports and technology transfer, privacy, trademark, commercial codes, and employment law, etc. Commercial or contract law enters in as well in connection with such issues as formation, interpretation, warranties, and remedies for breach. Choice of law and choice of forum are issues as well in our present global marketplace. Thus, content licensing is a complex legal subject necessitating review of the applicable law both creating intellectual property rights and governing contractual agreements and licensing.

INTRODUCTION

Content licensing primarily concerns the licensing of property, which itself consists of certain legal rights. Besides copyright law, content licensing takes place within the context of rights and obligations stemming from an array of local, national, foreign, and international laws. Such law may concern author or creator's "moral rights," "neighbor rights," lender's rights, defamation, privacy, publicity, pornography and obscenity, international trade, exports and technology transfer, privacy, trademark, commercial codes, and employment and contract law, etc.

To understand content licensing, copyright and other law must be juxtaposed with the law governing the formation, interpretation, warranties, and remedy for breach of contract. The issues are complicated by choice of applicable commercial law. While it is always prudent to consult an attorney with respect to negotiating, drafting, and litigating any contract, this is especially true with respect to the technical field of copyright law. Consequently, the topics and issues discussed in this entry are for informational purposes only and should not be relied upon in lieu of consultation with competent legal counsel.

WHAT IS A LICENSE?

A license is a contract, not necessarily in writing, in which one party (the licensor) transfers rights to use certain property to a user (the licensee) for some limited period of time or until some event. A permanent transfer of rights is an assignment or sale, even when the licensor retains other related rights (e.g., the transfer of rights to publish in print but not in any electronic medium). With respect to

intellectual property, a licensor may, but need not be, the creator, or even the owner, of the work being transferred.

By entering into license agreements, the parties seek to establish a mutually beneficial relationship in which they exchange certain promises or consideration (payment), set forth their respective rights and obligations, and provide for redress in the event of breach (i.e., a failure of one or more of the parties to meet their obligations). Besides license to use property for a given term, the licensee may seek certain warranties (guarantees) from the licensor, that the person has title or the rights to the content being licensed, and that additional payments or liability to third parties will not result from licensee's use of the property. As used in this entry, content licensing refers to license agreements affecting informational content and the software necessary to access that content.

One principal difference between licensing content and purchasing information in a print publication is that the "first sale" doctrine generally does not apply.^[1] The first sale doctrine cuts off the right of owners to seek additional remuneration each time a work is subsequently sold or lent to another.^[2]

WHAT RIGHTS MAY BE ADDRESSED IN A LICENSE AGREEMENT?

Although it may be said that all property consist of rights, in the case of intellectual property (^[2] at 813) such property owes its existence to rights enumerated in the law, and often by statute. The right to license intellectual property interests may potentially originate in the law of copyright, neighboring rights, moral rights, and electronic rights, etc. Several of these respective sources of

intellectual property rights frequently addressed in content licensing agreements are considered below.

Copyright Law

In the United States, such rights are found in Title 17 of the United States Code (USC) § 106 and include rights to:

1. Reproduction;
2. Adaptation (or “derivative works”);
3. Distribution (including “sale or other transfer of ownership, or by rental, lease, or lending”);
4. Public performance (limited to “literary, musical, dramatic, and choreographic works, pantomimes, and motion pictures and other audiovisual works”);
5. Public display (limited to “literary, musical, dramatic, and choreographic works, pantomimes, and pictorial, graphic, or sculptural works, including the individual images of a motion picture or other audiovisual work”); and
6. Digital audio transmission (limited to sound recordings).

In addition, 17 USC § 201 (c), sets forth rights of publishers of “collective works” in relation to the rights of contributing authors. Specifically, publishers of collective works have the right to publish contributed articles in “revisions” of the original collected work (e.g., a second edition of the same encyclopedia) and in any “later collective work in the same series” (e.g., a subsequent reprint of an article in the *same* journal). In the European Union, the EU Database Directive provides protections for publishers of databases.^[3]

Enumerated rights, such as those expressed in U.S. federal copyright law, form the basis for property rights assigned pursuant to licensing agreements. Similar rights may also be found in the common law of the various U.S. states and the law of foreign nations. Each of these rights may serve as the basis for an assignable property right and may further be limited in seemingly infinite variations by terms set forth in the licensing agreement (by time, jurisdiction, medium, types of uses, etc.).

Neighboring Rights

Besides copyright law, additional rights affecting licensing agreements stem from other law, including state law and the laws of foreign nations. For instance, many civil law jurisdictions such as France (and California, alone among U.S. jurisdictions), provide for neighboring rights (*droit de suite*), or rights designed to compensate artists for subsequent resale and reproduction of their works (traditionally, the law presumed that the reproduction rights to the works of fine artists had been transferred to the buyer of that painting, sculpture, etc., whereas the rights to literary works had not).^[4] In California, *droit de suite* is

applied through the California Resale Royalties Act.^[5] The Berne Convention, which was adopted by the United States in 1989, recognizes *droit de suite*. Unlike many other rights protected by the treaty, *droit de suite* requires that an author’s country recognizes the right. In addition the convention’s provision recognizing the right may not be “self-executing” under U.S. law (i.e., applicable without enabling legislation).^[6]

As a result of neighboring rights, licensees often seek express warranties in licensing agreements whereby the licensor warrants that the person not only has the right to lease or title to the licensed property, but that licensed use (or acquisition) of such property by the licensee (or purchaser) will not result in liability as the result of neighboring rights that any third (noncontracting) party may have. In addition, licensees often require an indemnification clause in the agreement whereby the licensor agrees to fully compensate the licensee as a result of liability to third parties.

Moral Rights

In many countries, under the Berne Convention, and to some extent in the United States, but only with respect to visual artists, there is a distinctive category of rights known as “moral rights” or *le droit moral*. This bundle of rights varies by legal jurisdiction, but can generally be enumerated:

1. Attribution or paternity (including the rights to be identified as the author, free from false attribution, and to publish anonymously or pseudonymously);
2. Integrity (to prevent derogatory substantive changes to the work);
3. Disclosure (or nondisclosure), reconsideration, and withdrawal (from circulation); and
4. Association (or disassociation of the work from products or institutions distasteful to the author or artist).^[7]

In many jurisdictions, moral rights are noneconomic rights. Whether or not such rights in property can be alienated, waived, or can survive their authors and creators depends upon the law of the jurisdiction being applied. The Berne Convention recognizes rights of attribution and integrity, but it leaves it up to signatory members how to protect such rights. Furthermore, the convention does not require such rights to be inalienable, “unwaivable,” or to survive the death of the author or creator.^[8] Under the convention, foreign authors and artists enjoy the same rights as native citizens in nations adhering to the convention.

Under the U.S. Visual Artists Rights Acts of 1990, now 17 USC § 106A, moral rights are addressed with respect to “visual art,” but only with respect to rights of attribution and integrity. In addition to U.S. federal law, several states have adopted moral rights, but to the extent such rights

concern the attribution and integrity rights of visual artists, state law is preempted by the federal statute.^[9]

France and Germany each represent yet two different conceptions of moral rights (in addition to the U.S. viewpoint). In France, moral rights are separate from economic rights, and consequently, cannot be alienated, and have no set term.^[10] In Germany, the duality of rights (economic and moral) is not recognized. Rather the approach is to prohibit the complete assignment or transfer of rights, and the term of the rights is set by statute.^[11]

The impact of moral rights on licensing agreements, to some extent, depends upon whether such rights may be waived, assigned, or limited under applicable law. Regardless of the validity of such limitations, however, licensees seek warranties that the licensor has not infringed upon any third party's rights and that the intended use per the agreement will not infringe upon such rights. In addition, the licensor may seek similar assurances that the licensee will not infringe upon any third party's moral rights (e.g., by removing attribution information, etc.). Per an indemnification clause, each party may also seek compensation for any liability resulting from infringements by the other.

E-Rights

With the development of the Internet and other information technologies, some have questioned whether "e-rights" constituted a new class of rights. While the U. S. Supreme Court decision in *New York Times v. Tasini* found that e-rights (in that case rights to republish the work of freelance journalists in a searchable database) do not automatically vest with print publishers, a closer reading reveals the real issue decided by the Court. That issue was whether, in that instance, the electronic database constituted a revision of the earlier collective, print work (which would favor the publisher, as an exception to infringement for "collective works" under 17 USC § 201 (c)), or a new work (which would favor the freelance journalists). Under 17 USC § 201(c), publishers of "collective works" acquire the right to reproduce and distribute a "particular collective work, any revision of that collective work, and any later collective work in the same series." The Supreme Court found that the database, which included many collective works (and not just a digital version of the original collective work), and provided access to each freelance article individually and separately, was indeed a new work.^[12] Thus, under *Tasini*, the issue is not whether e-rights are distinctive, but whether a database is considered a "revision," or falls within another exception for publishers of previous collective works under 17 USC § 201(c).

The Second, Ninth, and Eleventh Circuits have followed *Tasini*'s lead in utilizing traditional copyright analysis to determine rights in e-content. For example, in

Faulkner v. National Geographic Enterprises, Inc.,^[13] plaintiff authors sued National Geographic when it published a compilation of all previous issues in CD-ROM format, through which the original content appeared in its original context, albeit in a different medium. Like the *Tasini* court, the Second Circuit focused on whether the CD-ROM constituted a compilation, or a revision of a compilation, within the meaning of § 201(c) of the Copyright Act. Because the CD-ROM presented the "underlying works . . . in the same context as they were presented . . . in the original versions," which had not been the case in *Tasini*, the Second Circuit held that the CD-ROM was a "privileged revision" (^[13] at 38). In similar litigation also involving National Geographic, the Eleventh Circuit very recently reached the same result using a § 201(c) analysis.^[14] The Ninth Circuit looked to §§ 101 and 106 of the Copyright Code in *Perfect 10 v. Amazon.com*, which involved slightly different, but similar, issues arising out of thumbnail images and redirected access to copyrighted images through Google's Image Search feature.^[15] Using traditional analysis, the court found that thumbnail images were "fair use." Thus, these post-*Tasini* courts have not treated e-rights as separate or distinct, but have continued to apply traditional copyright analysis.

E-rights, to the extent that they represent rights in media created by new technologies, serve as a reminder of the importance of carefully identifying (with the assistance of competent legal counsel) what rights are subject to a licensing or assignment agreement. Careful attention needs to be given to new and unforeseen media that may result from new technologies. It follows that the greater the breadth of rights being licensed or assigned, the greater the compensation that may be expected. To assure the rights are being discretely bargained for, and thus do not include non-enumerated rights, each right or use should be identified with corresponding consideration, and a statement as to who holds the unnamed rights (including rights in any new media) should be included (^[7] at 103–104).

APPLICATION OF COMMERCIAL LAW

In addition to law governing the creation of intellectual property rights (such as copyright), licensing transactions are governed by commercial law (i.e., law governing contracts). Other law may apply as well, such as consumer protection statutes, labor relations codes, professional codes of conduct, bankruptcy and debtor–creditor law, and trade law. Because it is generally in the interest of commercial transactions to promote predictability and uniformity, uniform and model commercial codes are important as sources for law governing licensing transactions.

What Law Applies

In the United States, state law largely governs contract and commercial law through a series of uniform acts known as the Uniform Commercial Code (UCC), promulgated by the National Conference of Commissioners of Uniform State Laws (NCCUSL). For transactions involving “computer information,” a special uniform or model act was prepared in 1999, known as the Uniform Computer Information Transactions Act (UCITA). Amendments to UCITA were introduced and considered in 2000 and 2001; in 2002, NCCUSL approved the final revisions and amendments to UCITA and recommended it for enactment in all the states.^[16] As of summer 2007, only Maryland and Virginia have adopted the act.^[17] UCITA is controversial, and Iowa, North Carolina, West Virginia, Idaho, Vermont, and New York have passed or introduced legislation refusing to apply UCITA to contracts with their citizens.^[18] In addition, a committee of the ABA has recommended that UCITA be rewritten.^[19] In spite of UCITA’s widespread rejection, given the need for a uniform law and the impact of the UCC, not only in the United States, but also on commercial codes throughout the world, UCITA (or its progeny) may yet become an important source for the construction and interpretation of digital licensing agreements throughout the world. If nothing else, UCITA represents an important effort to address the multitude of issues pertaining to content licensing and computer information transactions.

To the extent that a U.S. state has not adopted UCITA, then often UCC Article 2 applies. In varying degrees, state courts in Connecticut, Kansas, Massachusetts, Georgia (applying Michigan law), Nebraska, New York, and Tennessee have applied UCC Article 2 to computer software licenses. Likewise, federal courts in California, Florida, New Hampshire, New Jersey, and Pennsylvania have interpreted the laws of their respective states to apply UCC Article 2, and federal courts in Michigan and Kansas have applied Illinois and Wisconsin UCC law, respectively.^[20] Because many software licenses involve the licensing of both goods (the software product) and services (technical, customer support, and client-specific programming), many courts weigh whether the services or the goods predominate.^[21] The question of whether software has been designed as a service (to which UCC Article 2 has been found not to apply)^[22] or whether it is a product customized for a particular user or includes installation and other services (to which the UCC has been applied)^[23] is one that requires careful weighing of all the pertinent facts. In addition to UCC Article 2, Article 2A, governing leases, has been adopted in 49 states and the District of Columbia. The sole state yet to adopt Article 2A is Louisiana, which has also declined to adopt Article 2.^[24] Because of the similarity of leases to licenses in terms of transfers of rights or use and possession, but not ownership, one may speculate that UCC Article 2A will become

the dominant law governing content licensing agreements (assuming UCITA is not widely adopted).

In August of 2002, proposals to amend Articles 2 and 2A of the UCC to exclude “information” from the definition of “goods” were submitted to the NCCUSL.^[25] Such a definition of “goods” would mean that neither Article 2 nor 2A would apply to most information transactions. Somewhat surprisingly given the historical resistance of UCC Article 2 to amendment, the proposed changes were adopted in 2003. Currently, in defining “goods,” Articles 2 and 2A both specify that “[t]he term does not include information.”^[26] The Official Comment to Article 2 acknowledges, however, that transactions often include both goods *and* information, and that it will ultimately be up to courts to determine whether, and to what extent, Article 2 should apply.^[27] As of summer 2007, Oklahoma is the only state that has incorporated this change into its commercial code.^[28]

At present there is no treaty or convention expressly addressing computer information transactions in the same manner as UCITA. The European Union’s EC Legal Advisory Board has expressed considerable hesitation and reluctance to fashion their own law after UCITA. Principally, concern has been expressed over whether UCITA, even if adopted, will be done so on a uniform basis because of some of its controversial provisions and approach: acceptance of click-wrap agreements (via electronic agents), choice of law, focus on software (rather than other forms of intellectual property), and the acceptance of denial of access and electronic self-help as remedies for breach.^[29]

The UNCITRAL Model Law on Electronic Commerce addresses admissibility of electronic documents, electronic signatures, and “data messages” pertaining to the sale of goods, but not on the licensing of copyright. Another law that may apply is the Convention on Contracts for the International Sale of Goods (CCISG) (however, unlike the UCC, the convention does not apply to “goods purchased for consumer purposes” meaning for “personal, family, or household use”).^[30] In addition, the European Directive on Unfair Terms in Consumer Contracts,^[31] the European Data Directive,^[32] and the European Directive on Legal Protection of Databases may also apply.^[33]

Writing Requirement and Requirements of Formation

Under UCITA § 201, the licensing of digital rights for transactions involving payment of \$5000 or more generally requires written agreement. With respect to transfers in ownership, U.S. federal copyright law under 17 USC § 204(a) requires written contracts. UCITA § 201 provides for exceptions to the written requirement, which exceptions are common to commercial contract law. Generally, no writing is needed when

1. The contract term is one year or less;
2. Performance has been tendered and accepted;
3. Such agreement has been admitted under oath;
4. Written confirmation of a contract is received between merchants and no objection is made within a reasonable time.

In addition to the requirement that certain contracts be in writing, there are other requirements to the formation of a valid license agreement:

1. Parties intent and basis for remedy;^[34]
2. Agreement as to material terms;^[35]
3. When applicable, a valid offer and acceptance.^[36]

Official Comment 5 of UCITA § 202 clarifies that if there is disagreement as to the “scope” of the license, there is no contract.

Because of the utilization of “shrink-wrap” and “click-wrap” agreements” (i.e., agreements that are accepted by clicking “yes” on prompted display of a license agreement as part of the loading or use of software or a computer service), UCITA devotes considerable attention to the use of “electronic agents” to manifest acceptance of an agreement. Sections 107, 112, 207, and 208, recognize shrink- or click-wrap agreements. Click-wrap agreements are recognized through electronic agents, which are defined under § 102(a)(27) as “a computer program, or electronic or other automated means, used independently to initiate an action, or to respond to electronic messages or performances, on the person’s behalf without review or action by an individual at the time of the action or response to the message or performance.” In other words, it is possible to manifest assent or acceptance of an agreement through automated means without written signature. An example of acceptance by electronic agent is found in Official Comment 4 of UCITA § 206: “Officer dials the telephone information system using the company credit card. A computerized voice states: ‘If you would like us to dial your number, press “1”; there will be an additional charge of \$1.00. . . .’”

Shrink-wrap or click-wrap agreements are permitted under UCITA §§ 112, 113, 208, and 209 under the following conditions:

1. The parties had reason to know at the outset that terms would be proposed for later agreement.
2. There is an opportunity to review the terms before assent is given (this may be after payment is tendered).
3. There will be assent involving acts or inaction taken with reason to know that it will create an inference of assent.
4. If the party does not assent, it has a right to a return and refund of any price paid, which right is cost free in a mass-market case.

5. In a mass-market case, the terms are produced and assented to at or before the time of initial use of the software.

Notwithstanding the validity of shrink-wrap and click-wrap agreements or acceptance by electronic agents, UCITA § 206(a) does grant courts discretion to fashion a remedy where the acceptance resulted from “fraud, electronic mistake, or the like.”

Some state consumer protection statutes may differ from UCITA in terms of their signature or record-keeping requirements. UCITA does not alter these requirements, but rather provides states the latitude to specify which such statutes are to prevail over UCITA provisions in case of a conflict.^[37] State consumer laws enjoy special status (for preempting terms of licensing agreements) under UCITA.

Other laws may also recognize shrink- or click-wrap agreements. While UCC § 2-204(1) provides that “a contract for sale of goods may be made in any manner sufficient to show agreement, including . . . conduct by both parties which recognizes the existence of such a contract. . . ,” U.S. courts are divided as to whether shrink-wrap agreements are enforceable.^[38] UCC § 2A-204(1), governing leases, contains an almost identical provision to Article 2. The CCISG permits electronic agreements (without a writing) unless one of the contracting states specifically mandates a writing requirement by excluding the applicable provision of the convention.^[39]

Finally, although yet to be ratified by any country, the Hague Convention for Choice of Court Agreements (CCCA), provides a liberal standard of contract formation: “by any . . . means of communication which renders information accessible so as to be usable for subsequent reference.”^[40] Under this standard, almost any “click-” or “shrink-wrap agreement” concluded pursuant to the law of a signatory nation would be enforceable.^[41] However, the CCCA exempts contracts entered into for personal or household purposes (^[41] at Art. 2(1)).

Enforceability of Contractual Terms against a Fundamental Public Policy or Conflicting with Other Law

The Eighth, Ninth, and Federal circuits have recently looked at the enforceability of “no reverse engineering” clauses included in shrink-wrap or click-wrap agreements. Faced with claims that such terms violate public policy in that they prohibit fair use, courts have generally held that those who agree to such license terms are bound by them.^[42] Courts have also rejected the argument that “no reverse engineering” clauses are preempted by the Copyright Act, finding that the mutual assent and consideration required by a contract claim provide an “extra element” that makes the right asserted qualitatively different from

the rights protected under the Copyright Act.^[43] Absent a license term that prohibits it, however, the Ninth Circuit has held that reverse engineering constitutes fair use, privileged under § 107, when “there is good reason for studying or examining the unprotected aspects of a copyrighted computer program.”^[44]

Under UCITA, a license agreement (or other contract) in which any term “violates a fundamental public policy” may result in the court finding that the contract is unenforceable or limiting enforcement to the remainder of the contract.^[45] In Official Comment 3 to UCITA § 105, a “shrink-wrap license” prohibiting the licensee from ever criticizing the software is seen as problematic. On the other hand it is expressly noted that such a provision might be accepted in a negotiated license where the license pertained to software in the early stages of development, which had not been released to the general marketplace.^[46] In addition, courts may refuse to enforce or limit the enforcement of contracts or terms that are unconscionable (generally, terms that are very “one-sided”).^[47]

Besides considering public policy, UCITA provides for the preemption of federal law and state consumer protection statutes.^[48] Other state law does not preempt private license agreements (unless explicitly considered by the state when it enacts UCITA). This is important because copyright and other rights contained in state law, which may be broader than federal copyright law, consequently do not preempt contractual agreements under UCITA.

Of particular concern is whether licensors of digital content can extend their rights that would otherwise be limited with respect to applicable federal copyright law (state law, except for consumer law, is granted a lesser standing to preempt terms of the license agreement under UCITA § 105). The act attempts to balance a fundamental policy of contract law to enforce contractual agreements with “public interest in assuring that information in the public domain is free for all to use from the public domain and in providing access to information for public purposes such as education, research, and fair comment.”^[49] Having said this, there is no question that UCITA fundamentally advocates the enforceability of license agreements. “[I]t is clear that limitations on the information property rights of owners that may exist in a copyright regime, where rights are good against third parties, may be inappropriate in a contractual setting where the courts should be reluctant to set aside terms of a contract.”^[50] Indeed, courts are particularly reluctant to set aside negotiated (as opposed to “mass-market,” “shrink-” or “clip-wrap”) agreements.^[51]

With respect to “mass-market” transactions, Official Comment 3 of UCITA § 105 suggests that license terms prohibiting the making of multiple copies, use of information for commercial purposes, limiting the number of authorized users, or modification of the software or content are generally enforceable.^[52] However, terms in a “mass-market” agreement that “prohibit persons from

observing the visible operations or visible characteristics of software and using the observations to develop noninfringing commercial products, that prohibit quotation of limited material for purposes of education or criticism, or that preclude a nonprofit library licensee from making an archival (backup) copy would ordinarily be invalid in the absence of a showing of significant commercial need.”^[53] Additional provisions are suggested for the circumvention of technical measures protecting copyright for purposes of checking security and to provide for the “interoperability of computer programs.” Finally, “to the extent that Congress has established policies on fair use, those can be taken into consideration under [UCITA § 105].”^[54] Consequently, policy articulated in the legislative history of the fair use provisions of 17 USC § 107 may have bearing on the enforceability of terms in license agreements that otherwise restrict the application of “fair use.”

Like UCITA, UCC Article 2 has a section addressing “unconscionable contracts.”^[55] It does not, however, have a specific section addressing conflict with fundamental public policies or consumer protection statutes. However, the UCC does not necessarily restrict claims of aggrieved parties to breach of contract under the UCC. For example, it is possible to bring a claim for breach of warranty under the UCC in the same action as claims based upon violation of a consumer protection statute provided that the consumer protection claim is not simply a restatement of the breach of warranty claim.^[56] Likewise, UCC Article 2A, governing leasing, and now adopted in 49 states, addresses consumer protection statutes but does not conflict with “fundamental public policy.”^[57] Article 2A also addresses “unconscionable” leases and terms.^[58] The CCISG, unless otherwise noted therein, expressly does not address the “validity of the contract or any of its provisions. . . .”^[59] Consequently, enforceability of terms that may be in violation of a fundamental public policy or unconscionable is a matter to be determined under national or local law pursuant to choice of law rules.

Choice of Law and Forum

Choice of law and forum matter because the outcome of a particular dispute may rest on the discrepancies of the law between jurisdictions. Under UCITA § 109, the law governing any agreement is generally the law selected by the parties per the agreement. However, this does not apply to “consumer contracts” (i.e., between a licensed merchant and consumer) to the extent that this would affect the application of any state law (such as consumer law) pursuant to choice of law rules under UCITA (assuming the absence of agreement as to choice of law).

If the parties have not specified what law applies by agreement, then the law of the licensor’s jurisdiction applies if the contract called for electronic delivery of the product or information, and the law of the licensee’s

jurisdiction applies if a delivery was designated by a tangible medium. In any other instance, the law of the jurisdiction with the “most significant relationship to the transaction applies.” As a final caveat, for an international transaction in which choice of law has not been determined per the agreement, the law of a jurisdiction outside the United States only applies if a party located in the United States would have “substantially similar protections and rights” to those found under UCITA. As indicated in Official Comment 5, this does not mean “merely that the foreign law is different,” but rather the “differences must be substantial and adverse.” Under UCITA § 110, choice of forum, the place where litigation of a dispute will take place, is also left up to the parties unless the choice is “unreasonable and unjust.” Official Comment 3 indicates:

“Terms may be unreasonable in that they have no commercial purpose or justification . . . and their impact may be unjust if the term unfairly harms the other party. . . . On the other hand, an agreed choice of forum based on a valid commercial purpose is not invalid simply because it adversely affects one party, even if bargaining power was unequal.”

In essence valid commercial purposes, such as a party’s location, will justify choice of a particular forum.

For those states that do not adopt NCCUSL’s recently changed definition of “goods,” which now excludes “information” (see ^[25] and accompanying text), UCC Article 2 applies Article 1, § 1-301, to determine choice of law for digital content agreements. Like UCITA, the UCC distinguishes consumer from other types of transactions, but otherwise gives deference to the choice of the parties regardless of whether the jurisdiction selected has a “reasonable relation” to the transaction. However, for consumer transactions, the selected jurisdiction must bear a “reasonable relation” to the transaction, and may not deprive a consumer of any protection under their applicable consumer protection law. Regardless of whether the transaction is a consumer transaction, per § 1-301, a choice of law clause is “not effective to the extent that application of the law of the State or country designated would be contrary to a fundamental policy of the State or country” whose law would otherwise apply.

In the absence of UCITA, and once again assuming that “information” is not excluded from the definition of “goods,” UCC Article 2A may become the preferred uniform law for interpreting content licenses. Under Article 2A, choice of law and forum clauses for consumer leases are limited:

1. If the law chosen by the parties to a consumer lease is that of a jurisdiction other than a jurisdiction in which the lessee resides at the time the lease agreement becomes enforceable or within 30 days thereafter or

in which the goods are to be used, the choice is not enforceable.

2. If the judicial forum chosen by the parties to a consumer lease is a forum that would not otherwise have jurisdiction over the lessee, the choice is not enforceable.^[60]

Consequently, under either UCC Article 2 or 2A, applicable consumer law of the party who is a consumer will generally always apply. Indeed, under Article 2A, the law of the party who is a consumer will always apply.

Although only applying to commercial (and not consumer) transactions, the CCISG, applies if both of the parties (which must be in different countries) are located in contracting states (to the CCISG), or if the law of a contracting state applies through choice of law rules.^[61] Having said this, parties may, per the agreement, elect out of the application of the convention.^[62] Since the convention neither applies to consumer transactions nor addresses the validity or enforceability of contractual terms,^[63] choice of law rules of the jurisdiction where the dispute is adjudicated have to be applied for many issues relating to international transactions. For U.S. courts, choice of law questions are increasingly decided based upon “significant relationship” of the jurisdiction to the transaction (even if the UCC is not considered). Certain factual contacts are weighed to determine if such a relationship exists:

- The place of contracting;
- The place of negotiation of the contract;
- The place of performance;
- The location of the subject matter of the contract; and
- The domicile, residence, nationality, place of incorporation, and place of business of the parties.^[64]

In addition several policy considerations are weighed:

- Maintenance of interstate and international order;
- Relevant policies and government interests of the forum;
- Relevant policies of other interested states;
- Relevant interests of those states in the determination of the particular issue;
- Protection of justified expectations (of the parties);
- Basic policies underlying the particular field of law;
- Certainty, predictability and uniformity of result;
- Simplification of the judicial task; and
- Application of the better rule of law.^[65]

For EU countries, the issue of choice of law is governed by the Convention on the Law Applicable to Contract Obligations (adopted in 1960), which generally honors the choice of the contracting parties.^[66] If no choice has been made by the parties, the law of the country “most closely connected” which usually defaults to the domicile or place of business of the party “who is to effect the

performance” (i.e., deliver the licensed product) (^[66] at Art. 4). Once again, certain exceptions are made for consumer contracts (defined as pertaining to goods or services outside of the buyer’s profession (^[66] at Art. 5).

Warranties

Warranties are additional promises made by the parties, usually pertaining to ownership of/or rights to the property being licensed, capacity to contract, outstanding claims for infringement, etc. Warranties may be specified by contract, but there are always certain warranties addressed in the applicable governing law on contracts. Under UCITA § 401(a), a licensor, who is “a merchant regularly dealing in information of the kind warrants that the information will be delivered free of the rightful claim of any third person by way of infringement or misappropriation. . . .” For other licensors (although also applying to merchants who deal in information), the warranty is limited: “no person holds a rightful claim to, or interest in, the information which arose from an act or omission of the licensor, other than a claim by way of infringement or misappropriation, which will interfere with the licensee’s enjoyment of its interest. . . .”^[67] Additional warranties (that the information is not in the public domain and that no other party shares in rights to the information) are made in the event that an exclusive license is granted.^[68] Warranties are not made with respect to the infringement of rights pertaining to collective administration (e.g., rights obtained through collective bargaining), or with respect to compulsory rights (certain limitations on copyright under U.S. law).^[69] Neither do UCITA’s § 401 warranties apply to informational rights arising under foreign law (unless the contract expressly provides for warranties under the laws of other countries *and* the rights originate in countries “under a treaty or international convention to which the country and the United States are signatories”).^[70]

The warranties set forth in UCITA § 401 can be waived or modified by agreement, but only if by “specific language or by circumstances that give the licensee reason to know that the licensor does not warrant that competing claims do not exist or that the licensor purports to grant only the rights it may have.”^[71] In an electronic or automated transaction, the language has to be “conspicuous.”^[72] Merchants have the option of “quitclaiming” rights without any warranty.^[73]

UCITA also applies for express warranties (additional promises made by the licensor)^[74] and, with respect to software, an implied warranty of merchantability (i.e., “fit for the ordinary purpose for which programs of that description are used”).^[75]

For content licensing agreements, a key issue is always whether there is a warranty as to the accuracy of information. UCITA § 404 distinguishes between licensors who are merchants “in a special relationship of reliance with a

licensee,” who collect and compile previously non-published information, and other kinds of licensors (editors or “conduits” for informational content). Essentially, the former are required to exercise “reasonable care.” In determining whether a “special relationship of reliance” exists, several requirements are articulated in the Official Comments to § 404, which comments attempt to capture doctrines already set forth in U.S. case law:

- Licensor possesses “unique or specialized expertise;”
- Licensor is in a “position of confidence and trust with the licensee such that reliance on the inaccurate information is justified;”
- Licensor is in the business of providing the type of information that is the subject of the transaction;
- Information is personally tailored to the needs of the licensee.^[76]

In addition, to the UCITA warranties for accuracy, other duties may be imposed on professionals (lawyers, physicians, etc.) based upon the law of the respective jurisdictions of their practice. The exclusion from warranty under § 404(b)(1) is for “published informational content,” which is “informational content made available to the public as a whole or to a range of subscribers on a standardized, not a personally tailored, basis.”^[77] The policy behind this exclusion is discussed on Official Comment 3. b. Regardless of UCITA or the UCC, claims brought against information and news services have been made under negligence rather than contractual warranty theory, and courts have found First Amendment reasons for not imposing liability.^[78]

Published informational content is the subject matter of general commerce in ideas, political, economic, entertainment or the like, whose distribution engages fundamental public policy interests in supporting and not chilling this distribution by creating liability risks. This Act treats published informational content that is computer information analogously to print newspapers or books which are not exposed to contractual liability risks based on mere inaccuracy; treating the computer informational content differently would reject the wisdom of prior law. Creating greater liability risk in contract would place an undue burden on the free flow of information. Once again, UCITA attempts to capture existing law as defined in the courts.^[79]

In addition to warranties concerning noninfringement, express warranties, and accuracy of information, UCITA also addresses implied warranties for compatibility with computer systems dependent upon whether the licensor “has reason to know any particular purpose for which the computer information is required. . . .”^[80]

Like UCITA, both UCC Articles 2 and 2A provide for warranties from infringement, express warranties and implied warranties of merchantability. Instead of providing for an implied warranty addressing system integration,

UCC Articles 2 and 2A each have an implied warranty for a “particular purpose.”^[81] However, there is a material difference with respect to UCC Articles 2 and 2A pertaining to warranties from infringement. Generally, Article 2 just warrants “rightful” title, and freedom from security interests, encumbrances, and liens.^[82] Article 2A, pertaining to leases grants freedom from interference with enjoyment (otherwise known as “the warranty of quiet enjoyment”) resulting from “a claim to or interest in the goods not attributable to the lessee’s own act or omission. . . .”^[83] The distinction is that “quiet enjoyment” includes the right to *use* and possess property without infringing upon third parties, whereas good title only refers to infringement as a result of the transfer of ownership (e.g., a transfer of title to a car may legitimately transfer ownership without guaranteeing that the car may be driven on state roads). This is a clear instance in which UCC Article 2A favors licensees. One can imagine litigation over whether Article 2A should apply to a transaction because the licensee argues that a particular use of the licensed information is covered under § 2A-211’s warranty of enjoyment. Like UCC Article 2, the CCISG requires transfer of good title (for intellectual property this warranty is limited to infringements of which the licensor knew or should have known),^[84] but there is no reference to a warranty for quiet enjoyment.

Like UCC Article 2A, UCITA warrants the “enjoyment” of the licensee’s interest from competing interests or claims “which arose from an act or omission of the licensor. . . .”^[85] Merchants who “regularly deal[] in information” have an unrestricted warranty of delivery that is free of third party claims for infringement or misappropriation (i.e., the infringement does not have to result from acts or omissions of the licensor). However, this higher standard for certain merchants does not encompass warranties of quiet enjoyment (which, for such merchants, still requires acts or omissions on their part).^[86]

However, since UCITA does not limit the warranty on merchants who “regularly deal[] in information” to their infringements resulting from *their own acts and omissions*, it provides better protection in some instances for licensees than Article 2A, but without explicit reference to enjoyment. Consequently, whether UCITA, the CCISG, UCC Article 2, or UCC Article 2A applies can have significant impact on the outcome of a dispute.

To illustrate this difference, imagine that a business subscribes to a database of fine art images from a commercial vendor who regularly sells databases of images from art museums and galleries. The license agreement says nothing about permissible uses of the images, and the initial subscription or access to images does not constitute infringement. The subscribing business uses an image as a background for the Web pages of its Web site. The owner of the image, a museum, informs the subscribing business that it is infringing on the museum’s rights by using the image on its Web site. Apparently, the museum had

licensed the images to the database vendor for educational purposes only, and the vendor was expressly obligated under its agreement with the museum to place a statement as to the educational limitation in any sublicense agreements, such as the one with the business (but failed to do so). The subscribing business to the database seeks redress from the database vendor for breach of implied warranty. Under UCITA § 401(b) and UCC § 2A-211(a), the database vendor may be held in breach of his warranty for quiet enjoyment. However, under both UCC § 2-312 and the CCISG Article 42, the database vendor is only in breach if it does not have good title, and it is unclear in this instance whether the database vendor’s failure to notify the subscribing business of any limitations for “educational purpose” constitutes failure of good title, especially since there are other permissible uses for the database. Since this section of UCC Article 2 has been applied to software,^[87] a legitimate issue is raised as to the potential for disparate treatment under the different uniform laws. This disparity may lead to “forum shopping” and greater use of contractual provisions that select the applicable law.

Remedies—Electronic Self-Help and Denial of Access

Although UCITA generally avoids functioning as a consumer protection statute, it does, in its final draft, completely ban the licensor’s use of electronic disabling devices or “self-help.”^[88] Termination of access for access contracts is permissible upon “material breach” of the agreement or “if the agreement so provides” without any other limitation under UCITA.^[89] Other remedies are available under UCITA including damages, cancellation, withholding payments, discontinuing access (for access contracts), repossession of all copies of the licensed information, etc.^[90]

UCITA’s use of electronic “self-help” (in early drafts where it was permitted) is really a reflection of UCC Article 9, pertaining to secured transactions, specifically the repossession of collateral.^[91] However, no analogous provision exists in UCC Article 2 or 2A or the CCISG. The propriety of such action is uncertain under case law. For example, a Minnesota case on the subject discusses claims (or counterclaims) against those invoking electronic deactivation of software; the court basically found that deactivation was appropriate because it comported with license terms to which the parties had agreed.^[92] In another case (although unpublished), claims based upon breach of warranty and the Computer Fraud and Abuse Act (CFAA)^[93] survived a summary judgment motion to dismiss.^[94] Subsequent case law ruled that the CFAA applies not just to hackers but to computer manufacturers as well.^[95] In yet another instance, a “drop dead” software device was found “void as a matter of public policy.”^[96]

Without the blessing of a uniform law such as UCITA, utilization of electronic self-help remedies such software deactivation and “drop dead” devices may subject licensors to liability. Even with UCITA, a significant legal issue is raised as to whether federal statutes such as CFAA or state or federal consumer protection statutes are superseded by UCITA with respect to electronic self-help.

As a kind of self-help remedy, termination of access, as provided for under UCITA § 814, does not have the same stringent requirements for exercise as electronic measures embedded in software under UCITA § 816. However, even the exercise of this remedy may be problematic if it conflicts with federal statutes or state consumer law.^[97] Nonetheless, the apparent greater latitude available for the termination of access remedy may propel vendors into exclusively providing content via online services.

CONCLUSION

Content licensing is a complex legal subject necessitating review of the applicable law both creating intellectual property rights and governing contractual agreements and licensing. In addition, consumer protection and other law may impact the transaction. Because of the nature of information transactions to involve a wide array of jurisdictions, choice of law has to be carefully considered with respect to international, foreign, and domestic (both state and federal) law. To add yet an additional layer of complexity, UCITA, a uniform law governing computer information transactions has evoked widespread opposition, and significant disharmony among jurisdictions. Nonetheless, UCC Articles 2 and 2A (and potentially, on a limited basis, the CCISG) may, on an increasing basis, fill some of the void left by UCITA. This is especially true of Article 2A, governing leases, assuming UCITA fails and that states decline to redefine their codifications of Article 2A to exclude information transactions.

Principal among the issues addressed by the various commercial codes and conventions are issues of formation, unenforceability, warranties, and available remedies in the event of breach. Particularly noteworthy (and worthy of scrutiny) are the attempts of such uniform laws to resolve issues surrounding shrink-wrap, click-wrap, mass-market transactions, and the validity of provisions conflicting with copyright law (including the interest of the public in “fair use”); other state and foreign intellectual property rights (which may be broader than, for instance, U.S. federal law); and state consumer laws. In addition, the enforceability and desirability of choice of law and forum provisions, the scope and validity of both implied and explicit warranties, and the potential for abuse and disruption potentially caused by remedies such as denial of access and electronic self-help through means such as disabling devices in software need to be resolved.

Digital Divide and Inclusion

Mark Warschauer

School of Education, University of California, Irvine, CA, U.S.A.

Melissa Niiya

Portland Public Schools, Portland, Oregon, U.S.A.

Abstract

The term “digital divide” is used to describe unequal access to computers, the Internet, and online information, whether among individuals, communities, or countries. Originally targeted at issues of physical access, such as whether people had a computer or Internet account at home, the concept is increasingly used to incorporate related issues, such as whether people have the skills and knowledge required to make effective use of digital media and information. A variety of initiatives have been taken within the United States and internationally to try to combat the digital divide.

INTRODUCTION

The term “digital divide” refers to the gap between those with access to computers, the Internet, and online information and those who lack such access. The digital divide has been discussed in relation to income group, race, ethnicity, age, gender, and language status among people within a community or country. Used internationally, it is often used to refer to gaps between countries that overall have greater access to information and communication technology (ICT) and countries with lesser access.

The term was originally used to refer to inequality in physical access, as represented by ownership of a home computer or having broadband Internet access. Soon thereafter, the term began to include other factors that enabled them to effectively use new technology, such as skills, knowledge, and social support.

This article will introduce the origin of the term in the 1990s and examine how the concept has evolved since it first emerged. It will review key facts about inequality in access to ICT, both within the United States and internationally, and discuss important individuals, organizations, and initiatives that have responded to this inequality.

HISTORICAL CONTEXT

Though the online communication dates back to the late 1960s, the Internet first became widely popular following the introduction of World Wide Web browsers in the 1990s. With this growing popularity, both officials and activists became increasingly concerned about the consequences of unequal access to ICT. In the mid-1990s, journalists and government officials in the United States began to describe this unequal access as a “digital divide.” *New York Times* writer Gary Andrew Poole used the term in

several articles in late 1995 and early 1996,^[1] and then both Al Gore and Bill Clinton used it in a speech in Knoxville, Tennessee.^[2] That same year, sociologist Manuel Castells published the first of three volumes on the information age.^[3] Castells’ three-volume work laid out the most compelling analysis to date of the critical role of information technology access and use in generating wealth, power, and knowledge in the current era.

Beginning in the mid-1990s, the term was used regularly by Clinton administration officials, especially by Larry Irving, Assistant Secretary of Commerce and Director of the National Telecommunications and Information Administration (NTIA). The NTIA published national studies in 1995, 1998, 1999, 2000, 2002, 2004, 2007, 2010, 2011, 2013, and 2014 that attempted to measure technological inequality in the thorough analysis of U.S. census data on computer ownership and Internet access as differentiated by race/ethnicity, income, gender, employment status, disability status, and urban/rural location.^[4] These research efforts were backed by policy initiatives, including the E-Rate program, which has provided funding to assist Internet connectivity in schools and libraries since 1996, the Federal Community Technology Centers Program, which provided substantial funding for local technology training and access in fiscal years 2000 and 2001, and later the National Broadband Plan, which aimed to use stimulus funds to bring broadband connectivity and technology education to underserved populations, particularly in rural areas in 2009–2010.

Just as steps were being taken to address the digital divide in the United States, international leaders and organizations became increasingly concerned about a global digital divide between rich and poor countries. The Group of 8 (G8) formed a Digital Opportunity Task Force in 2000 that brought together teams from government, the private sector, and nonprofit organizations in developed

and developing countries to identify ways to spread the benefits of the digital revolution more broadly.^[5] The following year, the United Nations Information and Communication Technologies Task Force was launched with a similar mission.^[6] The U.N. task force, still in existence today, organizes awareness programs, develops stakeholder networks, assists countries and regional groups with strategy development, supports broadened international participation in policy development, works to improve Internet connectivity around the world, and promotes efforts to support local content and application creation.

CONCEPTIONS OF THE DIGITAL DIVIDE

Early conceptions of the digital divide focused on a binary distinction between those who had and did not have access to ICT as indicated by availability of an Internet-connected computer. However, these conceptions soon came under criticism on several levels. First, since people access and use ICT in a wide variety of locations and contexts, the notion of a binary divide, rather than a complex continuum, was portrayed as simplistic, and one that could lead to failure to recognize the diverse ways that different individuals and groups do connect to digital information. Second, ICT access does not have a one-way relationship causal to individual and social development, but rather two-way; higher levels of development enable more ICT access, and ICT access can enhance developmental processes. Finally, the focus on physical access to technology was seen as too narrow since there are many other factors, such as language and literacy ability, computer skills, suitability of online content, and availability of instruction or social support that enable or constrain meaningful ICT use; any efforts to overcome inequity related to technology thus need to take these broader factors into account, rather than merely supplying additional hardware.^[7,8]

Today, there is broad recognition that the digital divide must be understood as incorporating a broad range of variables. A number of models have been developed to portray the factors involved in meaningful technology access and use, such as the one by Warschauer seen in Fig. 1.^[9]

Finally, some prominent individuals and groups have downplayed the notion of a digital divide. Michael Powell, chairman of the U.S. Federal Communications Commission from 2001 to 2004, compared the digital divide to a “Mercedes divide,” suggesting that ICT represented a consumer product that people could purchase or not depending on their wealth and desire and that government had little interest in promoting equitable ICT access.^[10] This view was echoed by the U.S. Heritage Foundation, which claimed that the free market will rapidly erase any digital divide in the United States and that government action would thus be counterproductive.^[11]

MEASURING THE U.S. DIVIDE

A variety of approaches have been developed for measuring the digital divide, both within and across countries. Within the United States, the early standards on this issue were largely set by the NTIA, whose national reports were broadly seen as the authoritative source of information on the topic. The reports were based on the Current Population Surveys (CPS) of about 50,000 U.S. households conducted by the Bureau of Labor Statistics and the U.S. Census Bureau. The CPS collect general demographic data on a monthly basis and supplement that with specialized data at different times; supplemental data on computer and Internet access were collected on six occasions between 1994 and 2003 and formed the basis of the NTIA reports.^[12]

The 1995 NTIA report focused on the question of whether U.S. households had either 1) a computer (i.e., *computer access*) or 2) a computer, a modem, and subscription to an online service (i.e., *Internet access*).^[13] Computer and Internet access were then compared by

Fig. 1 A model of factors affecting technology access and use.

geographic region and by the income, race, age, and educational attainment of the head of household. The 1998^[14] and 1999^[15] reports used a similar methodology, though the latter also added an additional variable of having an e-mail account (i.e., *e-mail access*).

The 2000 NTIA report continued to include comparative household data, but also included for the first time data on individual use, again compared by demographic variables. This shift represented an emerging recognition that any true measure of the digital divide needed to account for not only whether one had physical access to the technology but also whether one actually used it. Also for the first time, the 2000 NTIA report included the category of disabled status, thus drawing attention to an important dimension of the digital divide.^[16]

As home computer and Internet access continued to expand, the NTIA further de-emphasized household access and instead discussed individual use in more detail. For example, the 2002 report compared different types of Internet use (e.g., finding health information, finding financial information, entertainment-oriented activity) by the gender, age, race, and income of users; began to investigate who had broadband access to the Internet (though differentiated only by urban/rural location); examined types of computer use at work by the occupation of the user; compared amount of Internet and e-mail use at work by occupation and by gender; looked at whether diverse groups of children used computers at home, school, and other locations; and examined Internet use among particular categories of the disabled (e.g., blind, deaf, difficulty walking).^[17] The 2004 report indicated Internet use in relationship to broadband access and other demographic factors (e.g., gender, race/ethnicity, employment, income, education, age, and particular types of disabilities).^[18]

Beginning in 2013, the U.S. Census Bureau collected data on ownership of computers, smartphones, and other devices, as well as Internet access and type (e.g., broadband, dial-up, fiber optic), and has since provided these data on a yearly basis at the national, state, and, in some cases, city-specific level.^[19] These census data have revealed smaller gaps across race in terms of Internet use on smartphones.

Other groups have collected a range of data on Internet use that is helpful for understanding technology and equity. The most important of these groups is the Pew Research Center's Internet & American Life Project, which conducts random digit-dial telephone surveys on a wide variety of topics related to Internet use. Topics addressed by the Pew project include home broadband adoption, the use of the Internet for particular kinds of pursuits (election news and activity, health information), typologies of Internet users, and uses of the Internet by particular demographic groups (see Table 1).^[20] Data from NTIA, Pew, and others thus presents the following overview of the digital divide in the United States in relationship to particular demographic groups.

Table 1 Demographics of U.S. Internet users

	Use the Internet (%)
Total adults	88
Women	86
Men	89
Age	
18–29	99
30–49	96
50–64	87
65+	64
Race	
Caucasian, non-Hispanic	88
African-American, non-Hispanic	85
Hispanic	88
Geography	
Urban	89
Suburban	90
Rural	81
Household income	
Less than \$30,000/yr	79
\$30,000–\$49,999	90
\$50,000–\$74,999	95
\$75,000+	98
Educational attainment	
Less than high school graduate	68
High school graduate	81
Some college	94
College +	98

Source: Pew Research Group, Internet/Broadband Fact Sheet. <http://www.pewinternet.org/fact-sheet/internet-broadband/> (accessed May 22, 2017).

Gender: Differential computer and Internet access by gender had disappeared in the United States by 1997, and women and men continue to access the Internet to about the same degree. However, women receive only 18.2% of the computer science bachelor's degrees in the United States and encompass only 24.5% of professionals in information technology industries.^[21,22] These facts have led many groups to be concerned about the types of early experiences girls have with technology and whether these experiences are helping them develop the skills, knowledge, and attitudes to become leaders in technology-oriented careers.

Race/ethnicity: The race/ethnicity gap in Internet use has lessened over time, but it is unclear exactly how much. According to the most recent published U.S. Census Bureau information, 82.5% of Caucasian and 89.9% of Asian individuals live in a house with at least some Internet access, whereas only 71.1% of Hispanic and 67.3% of African-American households had an Internet connection.^[23] Pew Internet reports much smaller gaps, with a similar proportion of Caucasian (88%), African-American (85%), and Hispanic (88%) adults using the Internet, which could be due to the more recent dates of the data gathered (Pew in 2016 vs. Census surveys in 2013), or differences in methodology, with the Census data based on in-person visits to households and the Pew data

based on telephone surveys.^[20] In addition to different rates of Internet access, there appear to be differences in how different racial groups make use of digital media and the Internet, with African-Americans and Latinos disproportionate uses of social media and video streaming sites and Caucasians and Asians reporting more frequent use of the Internet for interest-driven content production practices.^[24–26]

Age: While the gap in Internet use between older and younger Americans is declining, age continues to be an important factor in the digital divide, with only 64% of U.S. seniors aged 65 or older using the Internet.^[20] Research suggests that income, cognitive ability, and the availability of relatives to help with technology are all factors correlated with whether and how seniors access the Internet.^[27]

Geography: Urban and suburban residents access the Internet to equal degrees. The gap between them and rural users has lessened in recent years and appears to be due in part to lesser access to broadband in rural U.S. areas; however, initiatives such as the Broadband Technology Opportunities Program have targeted these populations for increased broadband connectivity and education.^[28] Most recent data indicate that 81% of the rural population has broadband access compared to 89% of the urban population.^[29]

Income: Though all income groups have expanded their access to the Internet in recent years, income remains a major factor, with only 79% of those with household incomes under \$30,000 using the Internet compared to 98% of those with household incomes over \$75,000.^[20] Differences in quality of use are likely as well, due to the higher likelihood among families of having up-to-date computers, multiple computers, and broadband Internet connections than low-income families.

Education: Educational attainment is one of the most prominent factors of the digital divide, with 68% of those with less than a high school diploma or less education using the Internet and 98% of college graduates using the Internet.^[30] Differences in types of usage are also strongly correlated with education, with college graduates far more likely than others to use the Internet to enhance their productivity or manage digital content.^[31]

Disability: Disability status is also strongly correlated with Internet use, with only 62.5% of people with disabilities using the Internet.^[23] Limited mobility, limited income, and the high cost of specialized adaptive technology are all barriers toward people with disabilities using computers. Inconsistent implementation of accessibility standards in the design of online content also makes it difficult for people with certain disabilities, such as visual impairment, to make effective use of the Internet.

MEASURING THE INTERNATIONAL DIVIDE

Assessments of the international digital divide are usually made at the level of countries, or groups of countries,

Table 2 World Internet usage

Region	Percent of population using the Internet (%)	Usage growth, 2000–2016 (%)
Africa	28.7.3	7,488.8
Asia	45.6	1,515.2
Europe	73.9	485.2
Middle East	57.4	4,207.4
North America	89.0	196.1
Latin America/Caribbean	61.5	2,029.4
Oceania/Australia	73.3	261.4
World total	50.1	918.3

Source: Internet World Stats. Internet Usage Statistics. <http://www.internetworldstats.com/stats.htm> (accessed January, 2017).

rather than individuals. Indicators that are taken into account include the number of computers, Internet subscribers, or Internet users as a percentage of the population. Countries are then often aggregated by either region or continent for comparison purposes. For example, as seen in Table 2, dramatic differences exist between regions of the world in Internet penetration. Though regions with the least Internet access are expanding the fastest rate, it will still take a long time for them to catch up.

The international digital divide is also reflected in production of Internet content. An earlier study demonstrated that Internet domains are overwhelmingly concentrated in certain countries (e.g., the United States, Germany, and United Kingdom) and in major cities within those countries; follow-up studies have not been conducted to show how these trends may have changed over time.^[32]

The International Telecommunications Union (ITU) has attempted to develop a more complete measure of the international divide using a wide variety of indicators measuring network infrastructure (e.g., international Internet bandwidth), individual use (e.g., Internet users per 100 inhabitants), individual access (e.g., broadband subscribers per 100 inhabitants), and skills that enable computer and Internet use (e.g., adult literacy rates). It then brings this data together into an ICT Development Index (IDI) and groups countries based on this index into high, upper, medium, and lower levels. The ITU study found a huge gap between these different levels, with the divide steadily increasing further between the high and low extremes from 2001 to 2004. In 2004, the divide between high- and low-IDI countries began to decrease, suggesting the beginning of a small catch-up effect in overcoming the international digital divide. By 2007, IDIs had increased across all countries, and the gap between high- and low-IDI countries had slightly decreased, only to widen again in the subsequent 2011 reports.^[33,34] However, the gaps between developed and developing countries are now decreasing once again according to the groups' most recent report.^[35]

Researchers have also investigated the social, economic, and political factors that tend to correlate with the digital divide internationally. Studies suggest that general developmental level, amount of political openness and democracy, mass education, the presence of a sizeable service sector in the economy, and flexible telecommunication policy are all factors that correlate with Internet diffusion in particular countries.^[36,37]

The availability of mobile Internet connections has also contributed to increased Internet access and use. Some 95% of the global population lives within reach of mobile-cellular signal.^[35] However, the cost of mobile connectivity remains high in developing nations and is a major barrier to mobile phone ownership.^[35] Whereas about 80% of the world's population is using mobile phones, this falls to less than 60% in large developing economies such as Bangladesh, India, Indonesia, and Pakistan.^[35]

THE EDUCATIONAL DIVIDE

A good deal of attention on the digital divide has focused on the role of schools. Within the United States, for example, the National Center for Educational Statistics has carried out national studies since 1998 measuring Internet and computer access in public schools throughout the country. Though gaps between the number of Internet-connected computers in high-person of color (POC) schools (i.e., with 50% or more of their students being racial or ethnic minorities) and low-POC schools (i.e., with fewer than 6% of their students being racial or ethnic minorities) steadily fell from 1998 to 2002, it remained steady thereafter (see Fig. 2). In 2005, a study indicated that there were 3.0 students per Internet-connected computer in low-POC schools and 4.1 students per such computers in high-minority schools.^[38] More recent figures in 2009 suggest that on average there are 1.7 students per computer that can be brought into the classroom (such as via a shared laptop cart), with a slightly lower ratio in schools with less than 35% of students on free or reduced-price lunch (1.5 students per computer) and slightly higher in schools serving 50% or more students eligible for free or reduced-price lunch (1.8 students per computer).^[39] Though current data is not available, the widespread diffusion of low-cost Chromebooks is likely bringing these numbers down further. The digital divide in schools goes beyond the availability of computers and extends to how technology is used. African-Americans, Hispanics, and low-income students have been shown to disproportionately use computers for drills, remediation, and vocational education, whereas Caucasians, Asians, and high-income students more frequently use computers for advanced simulations and research.^[40] These differences are due to a number of factors, including the different levels of background, skill, and knowledge that

Fig. 2 Number of Internet-connected computers per student in high-POC and low-POC U.S. K-12 schools, 1998–2005.

Source: Wells et al.^[38]

students have; the differential amounts of technology they have at home (that may help them prepare for more advanced uses at school); and the different levels of skill and experience among teachers in low-income versus high-income neighborhood schools.^[39]

On the international level, little data exists as to the number of computers or Internet connections in schools around the world; however, obvious differences in these measures exist between developed and developing countries. Many developing countries think of schools as a critically important arena for overcoming the digital divide and are thus making efforts to outfit schools with computers and Internet access.

Schools have been a major focus for overcoming the digital divide. In the United States, the federal program known as E-Rate has made use of the Universal Service fee charged to telecommunication companies to distribute funds for schools and libraries to obtain affordable telecommunications and Internet access. Renewed in 2014 as the E-Rate Modernization Order, this program has expanded its goals to include provision of high-speed broadband, particularly Wi-Fi, in schools and libraries.^[41] Internationally, a number of countries, including Portugal, Peru, Uruguay, and Thailand, have carried out widespread distribution of individual laptops or tablets to children to attempt to increase technology access and educational equity.^[42–45] A number of prominent programs in this regard have been organized by the U.S.-based One Laptop Per Child (OLPC) program.^[46] Though OLPC extended computer access to the poor in a number of countries, it has also been criticized by some who believe that developing countries have more pressing educational priorities

than making large-scale investments in laptop computers for individual students, lack the infrastructure for basic utilities let alone Internet access, and too often do not have the resources to include teacher professional development and ongoing technological support for such initiatives.^[47] Research to date suggests that widespread distribution of computers to students without efforts to integrate their use into instruction fails to raise reading or mathematics test scores^[48] but may bring some more general cognitive benefits.^[42,49]

ADDRESSING THE DIGITAL DIVIDE

A number of programs have been put in place for addressing the digital divide. At the infrastructural level, programs have been launched to reduce the cost of computers or Internet connectivity for low-income citizens, for example, through providing free municipal wireless access. Other programs, such as the aforementioned OLPC initiative, seek to develop special versions of hardware or software that are both lower in cost and more suitable for use among the urban and rural poor.

As regards content, advocacy groups work to create online materials that reflect the economic or social needs (e.g., information about health care for low-income residents in the United States or local crop prices for rural farmers in India) and are available in multiple languages and dialects and at reading levels suitable for mass access. The development of technologies that enable self-publishing and collective content creation (e.g., wikis, blogs, and social media) has also enabled advocacy groups to work with underserved populations to promote inclusive participation in digital media production and to generate community-relevant educational materials.

As regards human capital development, initiatives have focused on making computers and the Internet more affordable to schools and for developing curricular and pedagogical approaches that ensure that all students have equal access to advanced forms of learning with new technology.

Finally, as regards social support, a number of governmental and nongovernmental organizations have promoted the availability of online population- and community-targeted resources for digital literacy education and to boost participation in digital media.^[50] Additionally, populations previously underrepresented in digital access and use have more and more been able to participate via mobile devices.^[51–53] However, some argue that lack of cultural capital means that—like computers and the Internet—access to mobile broadband alone is not enough to bridge the digital divide.^[53]

A number of grassroots groups attempt to coordinate information and organize, aimed at tackling the digital divide. Among these is the Digital Inclusion Network,^[54] which includes discussion lists, blogs, and event

announcements for educators, activists, policy makers, and others concerned with technology and social inclusion. Additionally, the Digital Media + Learning Central blog publishes case studies, articles, blogs, and educational resources promoting digital inclusion and ICT equity among global communities.^[55] A growing information and communications technologies for development (ICT4D) or development informatics community currently explores strategies for implementing information technologies as a means for spurring national development (e.g., see).^[56]

CONCLUSION

In the 1990s, governments and organizations around the world became concerned about unequal access to new technologies, whether among individuals or nations. Labeling this unequal access a *digital divide* helped draw attention to the issue. Since that time, the concept has broadened to address not only physical access to computers and the Internet but also the kinds of knowledge, skills, online content, and social support necessary to make such access meaningful. In that sense, there is not one digital divide but many, and diverse efforts on many fronts are needed to overcome them.

Digital Humanities

Julia Flanders

Elli Mylonas

Brown University, Providence, Rhode Island, U.S.A.

Abstract

Digital humanities is a recent and rapidly evolving field. It includes the range of activities and projects associated with the use of digital technologies for humanities research. Its roots lie in the 1960s with early work on digital texts and text corpora. With the emergence of desktop computing, use of computers for humanities research expanded in the 1980s, followed by the development of standards and the rapid growth of digital research projects and academic centers. In the 1990s, the rise of the World Wide Web made digital forms of publication increasingly common, and placed new emphasis on the value of networked information and online patterns of usage. The modern field of digital humanities has multiple forms of institutional presence, and embraces a range of characteristic methods, questions, and topics including information modeling, pattern discovery, standardization, and metadata.

INTRODUCTION

The field of digital humanities is a recent and rapidly moving target. There are several reasons for this: first, the fact that both of its putative two “sides” (humanities and digital technology) are themselves evolving swiftly, responding to cultural pressures and also to their own inner developmental logic. But in addition, their relationship is evolving. As digital technology moves into essential scholarly systems such as libraries, research and instructional tools, and methods of communication, the institutional juxtaposition of digital technology to the humanities disciplines has shifted. Where three decades ago, the technological infrastructure was housed and managed with visible and impressive separateness (and rarely used by humanists), it is now pervasive and unremarkable. Digital technology is no longer positioned as “science” or as “machine” but rather as media, as access, as enhanced modes of instruction, as a medium of collaboration.

The desktop revolution has made all of this possible by making digital technology cheap, user-friendly, and appealing to consumers. The ubiquitous connectivity of the Internet has also introduced new types of interaction and new participants in the humanities discourse. But this prompts an important question: how is digital humanities distinguishable from the routine (and expanding) use of desktop computing technology and the Internet for ordinary workday tasks? How does it differ from publications and research by nontraditional scholars and the general public? Is one doing digital humanities when one uses a word processor, or uses Flickr, or registers for an online seminar? If there is a clear difference, then it should be possible to describe—for funding agencies, for university administrations, and even ultimately for professional assessment—where that difference lies. It now appears

that digital humanities together with its various cognates is emerging as a distinct field of study – as suggested by the rise of departments, professorships and national funding programs using “digital humanities,” “humanities computing,” “humanities informatics,” and similar terms. If digital humanities, together with its various cognates, is to be considered an emerging field of study, then how can we most usefully characterize it and identify its boundaries?

This entry begins by providing a definition of digital humanities and a brief history, followed by a discussion of digital humanities in its institutional contexts, its relationship with digital libraries and finally, a short introduction to characteristic methodologies.

DEFINITION

Digital humanities can be understood both as a field in its own right and as a way of identifying digital research and project development efforts in specific humanities fields. More broadly, it also refers to any digital activity that furthers research in the humanities, or assists in the scholarly activities of its practitioners. Some of these activities may operate outside of any particular humanities field: for example, digital publishing or digital libraries.

As a discrete field, digital humanities studies the intersection of humanities ideas and digital methods, with the goal of understanding how the use of digital technologies and approaches alters the practice of humanities scholarship. In this sense it is concerned with studying the emergence of scholarly disciplines and communicative practices at a time when those are in flux, under the influence of rapid technological, institutional, and cultural change.

As a way of identifying digital interests and efforts within traditional humanities fields, the term “digital humanities” identifies, in general terms, any kind of critical engagement with digital tools and methods in a humanities context. This includes the creation of digital editions and digital text or image collections, and the creation and use of digital tools for the investigation and analysis of humanities research materials. It also includes the aggregation and arrangement of digital resources and tools in order to present humanities material to students, and other forms of broader dissemination. Finally, the term can be used to refer to tools, processes, and projects that expand access to the source materials of scholarship and teaching such as primary source texts, images, representations of artifacts, objects of study, and secondary source materials. In many cases, these expanded forms of access closely resemble their traditional counterparts, albeit with improvements of speed, accessibility, scope, and flexibility of use. These aspects of digital humanities can be expressed through conventional publication. But humanities researchers, accustomed to studying discursive modes, have also begun to seek experimental ways of embodying their work in new forms of digital publication. Examples include journals like *Vectors* and experiments with new models of scholarly publication such as *Hypertext in American Studies*, supported by *American Quarterly* and the Center for History and New Media.^[1,2]

It is useful to identify what we mean by “critical engagement” with digital tools a little more precisely. When an experimental digital tool first enters humanities practice, its methods of operation require significant user knowledge and are also subjected to critical scrutiny. However, as digital tools enter the realm of routine utilities, and develop surfaces that permit shallow rather than deep configuration, they become optimized for the most common uses. This optimization limits opportunities for critical engagement, by limiting access to information about their internal processes. In effect, as they become normalized and predictable, they become more like black boxes. This evolution mirrors the development of consumer tools in other technological areas. For example, automotive technology initially required the driver to have a detailed working knowledge of engines and to perform all configurations and repairs, thereby permitting the expert user to optimize the vehicle’s behavior (but also permitting mistakes and disasters). Modern vehicles allow the knowledgeable driver to make improvements and repairs, but do not assume this as a common practice. We can envision that the cars of the near future will be extremely high function, but only within the limits of the standard design, with no user-serviceable systems at all. Different digital humanities tools are at different stages in this evolution. Systems for authoring and publishing XML documents are just starting to enter the second phase, permitting but not requiring user configuration and expertise, whereas word processing systems have been at this

stage for over a decade. Some kinds of digital scholarly tools will probably never reach this point, but will always require significant levels of intervention from the responsible (and necessarily expert) user.

The question is whether this kind of engagement is, *ipso facto*, meaningful in a critical sense—in the sense of yielding important levels of disciplinary insight into methodology and process—or whether it merely seems meaningful at this incunabular stage of digital tool development because of the novelty of these processes. It is useful to recall in this context the intellectual significance Douglas Engelbart attached in the early 1960s to what we now regard as commonplace editorial functions like copying and pasting. The full description of the copy/paste process is worth quoting in full for its reminder of the historical distance traversed: “Adding one more light-pen pointing to what it took to delete an arbitrary string of symbols, Joe could direct the computer to move that string from where it was to insert it at a new point which his light pen designated. Again it would disappear instantaneously from where it had been, but now the modified display would show the old text to have been spread apart just enough at the indicated point to hold this string. The text would all still look as neat as if freshly retyped. With similar types of keyset and light-pen operations, Joe could change paragraph break points, transpose two arbitrary symbol strings (words, sentences, paragraphs, etc., or fragments thereof), readjust margins of arbitrary sections of text—essentially being able to affect immediately any of the changes that a proofreader might want to designate with his special marks, only here the proofreader is always looking at clean text as if it had been instantaneously retyped after each designation had been made.”^[3] Similarly, the use of online reference sources and journals is now taken for granted in humanities scholarship. The immediacy and comprehensiveness of these sources arguably has had a transformative effect on humanities research, but it would be harder to argue that it now has a significant effect on the intellectual or methodological content of that research.

There may thus be a critical window during which new tools expose their methodological significance to us, before they respond to the pressure toward commodification and the seamless interface required for general use. This would suggest that as digital humanities becomes established as a field, it will embrace both humanists for whom the use of digital tools is central to their regular research practice, and those for whom the exploration of tools and their impact on research methodology is itself of critical interest.

John Unsworth has suggested a definition which addresses this question from a different angle: digital humanities involves activities “in which the computer is used as tool for modeling humanities data and our understanding of it, and that activity is entirely distinct from using the computer when it models the typewriter, or the

telephone, or the phonograph, or any of the many other things it can be.”^[4] This formulation usefully relocates the idea of “meaningful engagement” away from the tool itself and onto the modeling activity the tool enables. It is not a question, in other words, of whether the tool itself resembles a modern automobile, but rather of whether our use of it resembles our use of the automobile: of whether we are capable of taking it apart and reassembling it as a spacecraft or a work of art. Tools and methods that look unscholarly or purely utilitarian at one point may over time be appropriated for scholarship in unanticipated ways; for instance, we are now beginning to see techniques from social networking sites such as del.icio.us and Flickr being incorporated into the design of scholarly digital publications. Examples include the experiment in folksonomic museum cataloging being undertaken at <http://www.steve.museum>, the ThoughtMesh project, and also the work of the NINES project.^[5,6]

The term “digital humanities” has emerged at least partly as a gesture of inclusion and an attempt to define a broader domain than was suggested by earlier terms such as “humanities computing.” But there are also several closely related fields which, though they share methods, interests, and populations with the digital humanities, can nonetheless be usefully distinguished from it. One of these is the field of new media (also, media studies), which contextualizes an interest in the digital within a broader set of concerns about media more generally. New media often combines a more strongly theoretical approach with a practical interest in multimedia production, and the field also engages more directly with domains like the visual arts and the performing arts. A second neighboring field is digital libraries,^[7] which sets shared interests (in meta-data, digital representation, and humanities content) within the context of library science issues such as information retrieval, knowledge representation, classification and cataloging methods. Digital libraries approaches are also framed by institutional priorities such as long-term sustainability, scalability, standard work flows, and cost-effectiveness.

HISTORY

Computing in the humanities began as a specialized practice which required access to scarce equipment. It was originally practiced by individual scholars who used it to perform their own research on literary or historical questions, and who published their disciplinary results in conventional venues. Subsequently, humanities computing became less concerned with the purely technical aspects of digitizing and analyzing digitized materials, and focused more on the preparation and representation of text collections and other objects of study. As this knowledge left the exclusive province of researchers and became a component of scholarly infrastructure like the library,

digital humanities has moved on to grapple with the social and collaborative aspects of computing, while continuing to explore aspects of text representation and text analysis. As it has matured, digital humanities has evolved from “humanities computing” which was defined by its reliance on and interaction with a computer to “digital humanities” which is concerned more broadly with media and methods in a digital context.

The earliest known use of technology to advance a discipline in the humanities was in 1949, when Father Roberto Busa approached IBM for help in creating a print concordance of the works of Thomas Aquinas and related texts.^[8–10] This was characteristic of early humanities computing, which replicated well-understood existing scholarly technologies such as concordances and dictionaries, but made their preparation faster, more accurate, and less tedious. There were no standards specifying how to encode a text for machine processing, which programming language to use, or even which hardware. Concordance programs had to be developed from the ground up, and although methodology was published and shared, the specifics of each implementation were unique.

Early humanities computing focused on indexing and analyzing texts, as the limitations of computers in the 1960s privileged character-based data. Early digitized text collections were usually small, and were not designed to be read online or disseminated electronically. Instead they represented a data set for processing: one step in the process of preparing a particular scholarly product. However, it was a natural progression to apply quantitative analysis to these data sets of literary and historical texts. This also fit into the data processing paradigm of computing that was prevalent at the time. Apart from Father Busa’s corpus of Aquinas, which took decades to be completed, most early humanities computing projects were applied to individual texts, and addressed specialized problems, for a single researcher. (In 1967, *Computers and the Humanities* listed 120 such projects under the category “Literature.”^[11]) Their results were published in conventional venues, books, and journals, and the “computerized” materials were not easily reusable by other scholars. Examples of this kind of processing were indexes, stylistic analysis, bibliographic compilations, and authorship studies.

By the late 1960s, we begin to see the appearance of journals and newsletters that document computer projects in the humanities (for example *Computers and the Humanities*, first published in 1966) followed soon thereafter by the founding of conferences and professional organizations (for example, the Association for Literary and Linguistic Computing was founded in 1973, and the Association for Computers and the Humanities was founded in 1978) that provided venues for sharing information, providing support, and creating the beginnings of a disciplinary identity. This increased sense of professional interconnection reflected important changes in the

scale and collaborative nature of digital projects. As computers became more standardized, centralized computer facilities appeared on campuses which allowed broader access and it became possible to acquire programs and materials created elsewhere. This made it feasible to justify paying for the development of larger corpora by pointing out the value of shared access to materials that could not be created for the use of a single researcher. Projects like the *Thesaurus Linguae Graecae* were initially funded by private donors, and were concerned from the outset with justifying the basis on which they selected texts and the ways in which they encoded them, so as to be acceptable to their destined audience in classics.^[12,13] Although not exclusively, work sprang from the disciplines with the most preexisting scholarly apparatus and with well-defined corpora of manageable size: religious studies, classics, Old English, and linguistics. Such disciplines were early users of computational tools to mediate their interaction with textual materials, partly because these tools reproduced and enhanced the utility of traditional research tools such as concordances and critical apparatus and perhaps partly because these fields are more hospitable to quantitative and empirical approaches to textual study. As computational tools elicited stronger mathematical forms of quantitative analysis, methodological disagreements (which had already separated the more philologically oriented field of Old English from the more critically oriented field of English literature) became more acute, alienating more traditional humanists from humanities computing.^[14]

Computerized texts also made it possible to print editions, concordances, and dictionaries more accurately and more efficiently. In the 1970s, with the development of corpora and the ability to output to typesetting equipment, it was possible to avoid rekeying texts with difficult formatting and unfamiliar character sets.^[15] Individual scholars and professional organizations like the Society for Biblical Literature developed specialized knowledge about fonts and typesetting, which was a digital extension of the scholarly apparatus they already applied to their discipline. Computerized texts could be repurposed, and used not only for generating indexes, but also for whole-sale printing of new editions.

In the early 1980s, this emerging emphasis on large-scale shared corpora and text processing tools was joined by a complementary trend: the emergence of desktop computing, with the introduction of the IBM PC (1981) and the Apple Macintosh (1984). The introduction of the graphical user interface helped to broaden the scope of humanities computing by making it possible to show images and display non-ASCII character sets. Specialized knowledge was no longer necessary to interact with a computer—word processing, and somewhat later e-mail, became part of the daily work of every scholar. The term “computing humanist” began to shift: from describing any scholar using a computer to perform research in the

humanities, to referring solely to those creating technology for the use of their colleagues in the humanities, or themselves exploring applications of technology in the humanities. As more scholars had access to computing, efforts were made to bring existing searching and analysis tools to the desktop [for example, tools like MicroOCP (Micro-OCP User Manual, Oxford University Computing Service: Oxford, 1988) and Conc (<http://www.sil.org/computing/conc/>)] as well as specialized word processing and textual editing software, targeted at the scholar, that mimicked the production of scholarly print editions.^[16] These tools did not form the mainstream of scholarly computing: they tended to be very specialized, with non-standard formats and user interfaces, and were difficult to share between different hardware and software platforms. However, by broadening the accessibility of scholarly computing, they helped to create an environment in which digital humanities methods could be discussed not merely as a novelty but as an emerging set of shared methods and practices. At the same time, they revealed a set of new opportunities and challenges. The overhead of having to prepare one’s own text for analysis, the difficulty of finding texts prepared by others, and the challenges of dealing with idiosyncratic markup systems were a substantial obstacle to scholars whose primary interest lay with the text and not with the digital methods themselves. On the other hand, the knowledge that scholars could make use of digital texts and other information at their desk, as they did conventional reference material, coupled with the graphical user interface, opened new horizons for translating conventional scholarly publication into richly linked, multimedia hypertexts.

In response to these limitations and challenges, two important developments emerged in the late 1980s and became more firmly entrenched in the 1990s. First, leading computing humanists who had been writing software and performing analyses on digitized texts, and who were aware of the lost opportunities and wasted effort due to the widely varying encodings applied to digital texts, gathered in Poughkeepsie, New York in 1987 to call for a standard encoding scheme for scholarly documents. This turned into the Text Encoding Initiative (TEI), which issued its first draft set of *Guidelines for Electronic Text Encoding and Interchange* in 1990, with the first major release in 1993. The guidelines were based on SGML, an emerging international standard, and have since evolved into one of the most influential components of digital humanities work. The process of developing the TEI Guidelines, and their application in specific projects, brought a wider range of humanities scholars into the field of humanities computing and opened up opportunities for digital text representation and analysis that went beyond the purely quantitative early approaches. It also raised issues of the relationship between language and its representation in text giving rise (perhaps for the first time) to theoretical questions about digital text itself, which contributed

importantly to the emergence of humanities computing as a research field rather than a way of getting things done.^[17–20] At roughly the same time as the development of the TEI *Guidelines*, other standards for humanities text encoding and metadata (such as EAD in the mid-1990s, to be followed by METS (Metadata Encoding and Transmission Standard) and related standards in the early 2000s) laid the groundwork for large-scale text digitization projects based on SGML and designed on a platform-independent and interoperable basis. Early examples include the Women Writers Project, the Victorian Women Writers Project, the Perseus Project, the Oxford Text Archive, the Canterbury Tales Project, the Piers Plowman Archive.

The other development was the dissemination of the work of Douglas Engelbart at Stanford and the writings of Ted Nelson on hypertext and hypertextual structures of information, and their application to knowledge work.^[21,22] Hypertext arose as a research area in Computer Science, and was implemented in several commercial and widely available software applications that ran on personal computers, the best known of which were Hypercard (Apple, 1987), SuperCard (Silicon Beach Software, 1989), and Guide (Owl, 1987). These applications allowed technical neophytes to create small, interlinked systems that could be used by their students and their colleagues. The parallelism of hypertextual structures with the literary theories of intertextuality and deconstruction resonated with scholars and instructors, and encouraged experiments in building self-contained hypertexts around particular areas of study: for example, Context 32, which turned into the Victorian Web (<http://www.victorianweb.org/>), and the Shakespeare Project developed by Larry Friedlander at Stanford University. The emergence of image and early multimedia capability on personal computers also permitted the use of non-textual materials. Projects like the IRIS Intermedia project at Brown University and the Perseus Project at Harvard University created multimedia digital content that could be used by other scholars and students. Several such projects are described in Delany.^[23] Although there was still no standardization of formats or software, humanities computing was now concerned not only with databases and textual analysis, but also digital dissemination and publication.

The World Wide Web, which was introduced in 1989, but whose potential became evident with the release of the Mosaic browser (1993), allowed all humanists with an Internet connection to be computing humanists by providing access to searchable corpora that were seamlessly linked to other relevant work. The WWW might be said to have made hypertext so common that it became invisible. Although the underlying structures and the linking mechanisms of the WWW were less powerful than what was available on desktops and in research software, they had several important effects: scholars, authors, and software developers were able to rely on a uniform infrastructure that allowed them to focus their efforts on their own

materials and presentation, the WWW's reliance on standards encouraged the development of standards in other areas, and the ability to link easily across Web sites and topic areas introduced the concept of collaboration as a scholarly tool.

The 1990s and the early part of the twenty-first century have seen both consolidation and further advances in all these tools and methods: a mixture of advanced experiments in desktop hypertext, scholarly editing, large corpus building and the increasing development and adoption of standards and guidelines such as SGML (which became XML in 1997),^[24] TEI,^[25] METS, and EAD,^[26] and the technologies that are based on them. At the same time, literary and media theorists have begun to engage with digital humanities projects, and have generated an increased awareness of digital art which tests the tropes of digital rhetoric. This has brought to the forefront a new research domain, the problematization of digital methods and systems. Heretofore, theoretical concerns had been situated in traditional disciplinary issues of scholarly editing, and analysis. Starting in the 1990s, media theory and critical theory find themselves sharing concerns.^[27–29] Finally, there has been a rise in international collaboration and the development of very large-scale digital infrastructure for humanities research.^[30]

INSTITUTIONAL LOCATIONS

What is suggested but not fully revealed in this history, as the field of humanities computing and digital humanities takes shape, is the important role of institutional location and funding models. Digital humanities projects find an institutional home in a variety of different contexts, and it is often these contexts that determine their scale, research agenda, personnel, and practical outcomes. For this reason, classification of digital humanities projects and work models can be a useful way of understanding the terrain. One such classification was developed in 2003 by Willard McCarty and Matthew Kirschenbaum and published by the Association for Literary and Linguistic Computing.^[31] This was repeated and expanded by the Centernet classification.^[32] It emphasizes the functional role of the various institutional centers: whether they provide teaching, research, collegial support, or technical support, or several of these in combination.

This classification leaves out some important sites of digital humanities activity (for instance, digital publication projects and individual research projects), and it also elides some useful distinctions. The category of “library-based units,” for example, includes both large-scale digitization efforts located within libraries, library units focused on managing electronic resources for patrons, and library projects with a more specific scholarly focus. This is not a failing in the classification itself but an expression of its intended purpose: to create a classificatory matrix that can

accommodate all humanities computing projects. But for purposes of understanding the broad outlines of the field and its evolution over time, we suggest an alternative classification that illuminates the most significant types of projects and takes into account the kind of intellectual product that motivates their design and activity. Naturally a given entity may occupy multiple spaces in this classification. The significant terms in this classification might be as follows:

- Digital library projects and centers which undertake the digitization of library collections on a large scale.
- Faculty support centers in which the goal is to enable humanities faculty (typically nontechnical or at least technically not self-sufficient) to use digital humanities technologies and approaches in teaching and/or research. Examples include the Institute for Advanced Technology in the Humanities (<http://www.iath.virginia.edu/>), HUMLAB (<http://www.humlab.umu.se/>), Maryland Institute for Technology in the Humanities (<http://www.mith2.umd.edu/>), Oxford University Computing Services (<http://www.oucs.ox.ac.uk/>), and the Scholarly Technology Group (<http://www.stg.brown.edu/>).
- Digital humanities research units in which central questions in digital humanities and its constitutive fields (human-computer interaction, digitization standards and practices, text encoding theory, new media theory, etc.) are pursued as the central activity; publications, projects, and funding initiatives emerge from this agenda. Examples include the Center for Research in Digital Humanities (<http://cdrh.unl.edu/>), CTB at the Royal Dutch Academy (<http://www.kantl.be/ctb/>), SpecLab (<http://www.speculativecomputing.org/>), STG, Women Writers Project (<http://www.wwp.brown.edu/>), and the Center for History and New Media (<http://chnm.gmu.edu/>).
- Digital humanities programs and departments in which digital humanities is the subject being taught (and where research is conducted as part of that effort). Examples include the Centre for Computing in the Humanities at King's College, London (<http://www.kcl.ac.uk/cch/>); English and Film Studies at University of Alberta (<http://www.arts.ualberta.ca/efs/research/dhrc.php>); TextTechnologie Department at Bielefeld, Germany (<http://coli.lili.uni-bielefeld.de/>).
- Digital publication projects, organized around the creation of a specific digital publication (often a scholarly edition or thematic research collection). Examples include NINES (<http://www.nines.org/>), WWP, and the Walt Whitman Archive (<http://www.whitmanarchive.org/>).

Some important relationships between these terms deserve closer attention. First, there are developmental processes by which one type of group will evolve into another.

Digital humanities research units, as they mature, may begin to resemble academic departments, particularly because the personnel they attract are already hybrids: technologists with advanced degrees in humanities fields or humanities faculty on a temporary detour from standard teaching jobs. This process in some cases results in a formal institutional transformation (for instance, the Centre for Computing in the Humanities at King's College London was converted from a support center into an academic department in 2006), and sometimes produces a group in which personnel occupy a dual role (for example, the senior staff of the Maryland Institute for Technology in the Humanities at the University of Maryland and at the Institute for Advanced Technology in the Humanities at the University of Virginia hold faculty positions). Digital publication projects may evolve into digital humanities research units, by attracting personnel for whom the research problems attendant upon the publication become an interest in themselves and provide an agenda that extends beyond the bounds of the original publication. Examples include the Women Writers Project at Brown University, which was originally founded to create digital anthologies of early women's writing but has evolved into a digital humanities research group; and the Walt Whitman Archive, which began as an electronic edition of Whitman's writings but similarly has gained critical mass in digital humanities research more generally. It now undertakes significant research on metadata usage and text encoding standards and has become the nucleus of a Center for Research in the Digital Humanities at the University of Nebraska. The reverse is also the case: research units and faculty support units often engender digital publication projects by providing support and impetus for faculty to undertake scholarly publication in digital modes. Finally, digital library centers often produce digital publication projects focusing on individual collections or authors of particular significance. Examples include the Robert Graves Diary at the University of Victoria (<http://graves.uvic.ca/>), the Chymistry of Isaac Newton at Indiana University (<http://webapp1.dlib.indiana.edu/newton/>), the New York Public Library's Digital Schomburg collection (http://digital.nypl.org/schomburg/images_aa19/), and numerous others.

There are also important structural alliances arising between entities in this list. Digital library centers and faculty support centers often find themselves in complementary (or potentially competing) roles in responding to faculty needs for digital materials. Depending on where digital services first arise in a given institution, facilities such as digital course reserves, digitization services, and support for digital publications or scholarly digital projects based on library collections may fall within the purview of either type of group. A clear mutual articulation of responsibility can be crucial in avoiding duplication, gaps in service, and territorial disputes. Along different lines, digital publication projects and faculty support centers

often depend on digital library centers for essential infrastructure, both technical and intellectual: metadata, cataloging, and digitization services, long-term archiving and digital repository management, and expertise in rights management and best practices.

DIGITAL HUMANITIES FROM A LIBRARY PERSPECTIVE

Thus far, we have been considering the field of digital humanities more or less as it considers itself. But from the perspective of the library community, the field presents a few specific faces of particular significance.

First of all, a very large proportion of large-scale digitization efforts in North America are being undertaken in libraries, or in partnership with libraries. The library community and in particular the academic library community are thus the places where attention is being paid to ways of making the resulting collections usable in a digital humanities context. Digital library staff are typically those charged with developing and implementing best practices for the use of metadata standards, and with producing and maintaining interfaces that permit these collections to be used effectively by readers. Already, experimentally, this use may include the ability to build new projects that draw and recombine materials from large digital collections, together with project-specific commentary or more specialized interface tools. And as we have already observed, a substantial number of digital humanities projects actually arise within libraries, arising either from faculty interests or from specific library collections (or both).

More importantly, though, libraries play a crucial role in the larger life cycle of the digital humanities. As we noted earlier, digital humanities tools and methods are constantly evolving from early experimental forms into routinized practices; as this happens, the kinds of support and implementation they require undergo significant changes. A digital tool or process in the incipient stages is initially adopted experimentally by a few adventurous practitioners; the required tools are installed as prototypes on a development server and programmers explore configurations, make optimizations, and work closely with faculty to develop cutting-edge projects that innovate both technically and intellectually. The results are often published as demonstrations of the potentially transformative effect the tool in question will have on humanities research. These activities typically take place within a digital humanities research group or faculty support center: groups devoted to small-scale, custom approaches that need not operate at scale to be effective as investigations. However, once the process in question is working smoothly and no longer requires attention (or poses interesting problems), such groups need to move on: their funding and institutional mandate require them to tackle new tools and processes, not to maintain well-established

projects at a production level, or to undertake their long-term preservation. As projects and processes enter a mature phase of active operation, a new set of needs arise: for the articulation of best practices, for cost-effective methods of executing work processes consistently and at scale, for anticipation of future needs such as forward migration of data, and for the provision of sustainable approaches to preservation and long-term access. These needs are entirely consonant with the traditional mission of libraries and it is in digital library centers that these needs are now typically being met. Because the library community is already primed to be aware of the importance of standards and best practices, they have led the digital humanities world in advocating, developing, adopting, and documenting standards and best practices in all areas of digitization.

Among these standards and practices a few of the most significant deserve specific mention:

- Metadata standards and specifically METS,^[33] MODS (Metadata Object Description Schema),^[34] EAD (Encoded Archival Description), the various name authority formats (MADS,^[35] etc.), and controlled vocabularies which form the basis for large-scale data management and retrieval. While these are typically not used directly by digital humanities projects, they provide an infrastructure on which many digital humanities projects rely at some point in their life cycle: for instance, when they enter a digital repository, or when they draw on digital materials from a digital library collection.
- Digitization methods such as digital imaging, OCR, automated scanning and markup technologies. Advances in this area are often driven by digital library needs, which are on a larger scale than other typical digital humanities projects.
- Aggregation and federation of data to permit cross-collection searching and other forms of functionality such as metadata harvesting. These are complicated infrastructural systems that can only be implemented by libraries, but they can be (and increasingly are) used by digital humanities projects and activities.
- Intellectual property rights management, and reciprocally the issues surrounding digital publication and the licensing of research materials such as online journals. Libraries have traditionally acted as institutional agents in these realms and continue to do so in the digital arena; additionally, however, as libraries play an increasing role as publishers of digital information, they also play a potentially transformative (or disruptive) role in the publication ecology and its cost structures.^[30]
- Information retrieval and knowledge representation, as these affect the design and implementation of large-scale systems for aggregating, processing, and using digital information in scholarly research. The field of

information science is merging into library science, specifically on the terrain of digital research materials. While these issues are by no means limited to the humanities, humanities data poses distinctive challenges and research requirements.

Finally, the rise of digital humanities activity and the increased resources that are being devoted to digital humanities projects mean that sustainability and long-term preservation of digital resources are rapidly becoming far from academic. Libraries are typically the place where digital repositories are being developed and housed, and the library world is the institutional space where issues of long-term archiving, metadata management, and forward migration are being tackled.

CHARACTERISTIC METHODS, PRACTICES, AND QUESTIONS

Modularity

The idea of a modular toolset or “scholar’s workbench” has preoccupied the digital humanities community for decades^[36] and has led to an interest in identifying the essential intellectual components of humanities scholarship and research. In a November 1995 posting to Humanist, Willard McCarty called for “a basic set of primitives” and a corresponding set of “component-packages”; “It seems to me that the most broadly useful invention would be a set of components the ‘garden-variety’ humanist could assemble quickly into a process.” (Humanist 9.301 <http://www.digitalhumanities.org/humanist/Archives/Virginia/v09/0278.html>.) Perhaps in recognition of the tendency noted earlier—by which methods and tools become “black-boxed” as they attain routine status—modularity of design has become an important paradigm for the digital humanities at a fundamental level. Its corollary is the concept of the application programming interface: the exposure of processes, of inputs and outputs, so that modules can be developed independent of one another and assembled by the practitioner in whatever combinations suit the task at hand. Its underlying logic is that of the open source, in which a published specification and open architecture permit extension and experimentation without artificial dependency or limitation.

For digital humanists, this modularity has two important goals. The first is, practically, to be able to model or represent these components in a combinatorial way in the digital arena; in other words, rather than prepackaging them in arbitrary and immutable combinations, to provide more granular or elemental tools which can then be used in whatever combinations scholars need. The second, more theoretically, is to be able to work on the difficult task of modeling these primitives themselves

digitally: not so much with the intention of producing tools, but rather of understanding the activities themselves more deeply.

The first goal has been tackled by digital humanities software developers. Willard McCarty gives as a notable example, the case of the Tübingen System of Text Processing Programs (TUSTEP),^[37] which provides for a sequenced set of tasks which are taken as fundamental to certain types of digital text processing: “capture, retrieval, collation, analysis, sorting, rule-based manipulation and output in digital or printed form.”^[38] But as he points out, the second goal is more challenging; mapping functional modularity onto the “functional primitives of scholarship” is not straightforward and in fact they do not correspond directly. These functional primitives actually turn out to require a different kind of modularization from what is in evidence in current tools. John Unsworth suggests what these might be: “discovering, annotating, comparing, referring, sampling, illustrating, representing.”^[4] Unsworth explicitly proposes these as a basis for a “useful tool-building exercise in humanities computing.” But as his subsequent discussion makes clear, the tools that arise to serve these needs are not focused in any simple way on sequencing these tasks or fulfilling them through a direct, modular implementation. On the contrary, he presents complex interfaces that integrate these functions as essential but not necessarily separable dimensions. In other words, modularity operates usefully at a conceptual level to help us understand the activities being supported or modeled, but at the level of implementation the units of modularization may be quite different.

Representation

Digital humanities as a field is deeply concerned with questions of representation, particularly as these impinge both on the digital representation “under the hood,” and on the way source material is offered for use to the reader. These questions sometimes loom as large theoretical problems. For instance, through what kinds of information structures can a digital object represent a material object or a time-based object? How do we measure the adequacy of a representation: through qualities like visual fidelity, or informational richness, or retrievability, or tractability to analysis?^[39,40] Does the form of the digital representation itself even matter, as long as its effects for the reader are serviceable? From another angle, the questions are methodological. What are the appropriate or strategically useful levels of granularity at which to represent data? What are the appropriate descriptive vocabularies and what are their characteristics? What is the strategically appropriate balance between, as Willard McCarty puts it, the “complexity and ambiguity” of the cultural source material, and the “mechanically rigorous” demands of computational form?^[41]

We can usefully identify several distinct (and often complementary) approaches to the representation of digital humanities information.

The first of these is modeling, which McCarty describes as the “performative” building of “hypothetical constructs” (p. 53)^[41] through which we can “make new knowledge” (p. 71),^[41] a process of “purposeful simplification” (p. 52).^[41] Modeling is thus an intellectual process which is not necessarily or even primarily digital, but which digital research methods bring to the fore. In this respect modeling recapitulates the relationship of critical engagement with the method that we observed earlier. McCarty notes the “mediating role and ternary relationship modeling establishes between the knower and known: the directed, vector-like engagement of the inquirer’s attention, through the model he or she has made to the object of study, and the model’s consequent function as an artificial agent of perception and instrument of thought” (p. 38).^[41] One measure of success here is the sophistication of the questions the model permits us to entertain, and its horizon of usefulness. Do we exhaust its intellectual potential and its ability to sustain questions immediately or over a longer period of time? Another measure is the range of different kinds of questions the model permits. Digital modeling technologies are typically those that permit complex data representation: databases, XML structures like TEI, METS, or SVG, metadata of various sorts, and data formats that represent spatial information such as GIS or CAD.

An opposed, or at least complementary approach, is what we might term the “facsimile”: representations that seek to reproduce the source more and more exactly according to some metric of fidelity. These metrics include, for instance, exactness of color duplication, granularity of visual detail, or fineness of sampling rate. Typically facsimiles appeal directly to some human sense: most frequently sight or sound, but we can imagine others becoming relevant with the advent of different output technologies catering to other senses. The measure of success for a facsimile is typically a level of accuracy, exactness of duplication, or sensory indistinguishability, rather than function. More precisely, the facsimile’s accuracy supports high function in the human brain through the human analytic processes that it enables, rather than functionality within the digital system.^[42]

The most common examples of facsimile approaches to digital representation are found in digital library collections that have been digitized as page images, often with metadata but without a corresponding transcription (either for reasons of cost or of transcriptional difficulty). In these cases, the facsimile simply offers an affordable way of providing basic access to rare or otherwise inaccessible materials for which transcription would be prohibitively expensive. However, for some projects the facsimile carries specific methodological merit as a way of representing visual (or other non-textual) information that

cannot yet be usefully modeled. The most vivid examples are the archives of visual artists such as William Blake or Dante Gabriel Rossetti, both of whom have prompted digital publications that not only rely on high-quality facsimile representations but also argue the limitations of modeling.^[42]

These arguments also reflect an increasing interest in the materiality of media and in particular of the source materials that are the objects of scholarly research. The modeling approach involves the complete absorption and transfiguration of the source’s informational content into a representation that is oriented toward some specific research problem. The facsimile approach suggests instead that there is an irreducible and resistant “thingness” to texts and artifacts that requires a more direct sensory interaction. The digital representation necessarily intervenes in this interaction (through sampling and the other reductions that take place in digitization) but it may do so to enhance some dimensions while it reduces in others. A good example is the work that has been done at the University of Kentucky’s *Electronic Beowulf*,^[43] where images of the damaged manuscript have been digitally processed so as to reconstruct damaged pages and make visible letters that could not otherwise be read. Processes such as digital flattening of folded or crumpled pages too brittle to be moved,^[44] or magnification and special lighting to reveal nearly invisible marks, suggest the ways in which a researcher’s apprehension of the material text itself is oddly more immediate and vivid—in some dimensions—when digitally mediated.

A third predominant form of digital representation is metadata, and in this category we can usefully also include the more traditional scholarly domain of commentary and contextualization. In an important sense, metadata is a more structured form of commentary: a way of formalizing our knowledge about an object and associating it with that object in a durable way. Under this informational rubric there is considerable variety. Some types of metadata are embedded within the digital object itself, such as EXIF or XMP data in a digital image file, or the TEI header in a TEI document. Other kinds stand outside the digital object and serve to catalog, manage, or situate it within a larger collection, or to manage information about some dimension of its content. Examples include METS, MODS, and the numerous formal standards for authority control. As the uses of metadata change with the growing importance of aggregation and cross-collection functionality, metadata is increasingly being managed apart from the digital object, pointing to it rather than being embedded within it, so that the distinction between embedded and independent metadata is less clear and less important.

Metadata plays a crucial role in the digital humanities, and particularly in projects and research tools in which scale is a critical component. For individual digital projects (such as a scholarly exploration of a single poem, or a multimedia installation, or an edition of a single text) the

need for metadata is minimal, and is focused on the requirement that such digital objects should carry with them basic information about their creation and status as publications, much as a book carries a title page and publication information. Best practice suggests that such objects should also carry further information about their preparation: the editorial principles that guided their creation, the relevant digitization standards, and methods of capture. This information, while not always strictly necessary for a reader, is probably useful for most critical readers. It serves the role of the discussion of methods that accompanies scholarly editions, and also serves the crucial purpose of facilitating future support or archiving of the digital object by an IT support group or a digital repository. Indeed, as soon as the object finds its way into institutional structures like these, it no longer functions in isolation but has to take its place in collections (increasingly large ones) in which its effective functioning will depend greatly on what kinds of metadata it carries or has added to it as part of its acquisition.

This transition illustrates an important tension in how metadata functions within the digital ecology. To the extent that the digital humanities domain aspires toward effects of scale (interinstitutional collaboration, large-scale aggregation of resources, cross-collection searching, reliable retrieval, analysis) it anticipates the value of metadata and invests significant resources in creating it, typically through partnerships with libraries or organizations devoted to creating standards and metadata aggregations (e.g., OAI). At the same time, as digital humanities reaches the scholarly desktop and no longer requires large-scale funding or groups of people to implement digital humanities projects, digital humanities activities resemble individual monographic publications, but without the publication infrastructure through which metadata in the print world has traditionally been supplied. In addition, the structure and even the medium of many digital humanities projects and publications leaves little space for metadata. For this reason, many of the digital scholarly products of the current era find themselves in publication (via the Web) without the levels of formal metadata control that were commonplace in print.

Pattern Discovery and Visualization

There has been increased interest in a new breed of text analysis tools which emphasize dynamic manipulation and pattern discovery rather than hypothesis testing and scientific approaches.^[45–49] The value of interactive systems was recognized much earlier; see for example Ben Shneiderman's 1983 discussion of "direct manipulation" which he defined as systems whose key features are "visibility of the object of interest; rapid, reversible, incremental actions; and replacement of complex command language syntax by direct manipulation of the object of interest."^[50] In the same vein, John Bradley contrasts what

he calls the "deterministic-transformational" approach to text analysis with approaches that consider "the effect of the machine on the development of a critic's *mental model* of the text" (187, emphasis in the original). McCarty, commenting on this entry, observes further that "Criticism is ... poorly supported by batch-orientated software, which being a 'black box' is by nature peripheral to what the scholar actually does" (219).

This emphasis on text analysis has led to significant research efforts in two directions: first, a resurgence of interest in large data sets that will permit meaningful literary text analysis, but with some differences from earlier corpus-building approaches: whole texts rather than samples; texts that are of significance to scholarship; markup used to represent genres and textual structures. And second, there has been a strong interest in developing tools that draw on data mining technologies drawn from the sciences and financial analysis to permit very large-scale pattern discovery. Currently the most prominent example of humanities data mining is the MONK Project (<http://www.monkproject.org>). These efforts are still nascent, but they offer significant potential to respond to real scholarly needs in the humanities rather than overlaying scientific investigative techniques onto literary content.

In concert with the development of the back end software and substantial corpora for analysis, visualization tools are also emerging as a crucial component of modern text analysis, but they have also arisen on their own as part of the fascination with Web 2.0 styles of graphical display and aggregations of data. From a digital humanities perspective, visualization tools fit well with the prevailing interest in modeling, since they provide ways of creating visual analogues to the representational models operating within the data itself, or within the researcher's own mind. Digital humanities visualization tools draw techniques from a wide array of sources: knowledge management tools, mapping, social networking tools, medical and scientific imaging, and virtual reality tools.

Future Trends

The developmental tendencies for the digital humanities field seem to run both toward increased disciplinary consolidation (through the emergence of departments, faculty, and degree programs) and also, ironically, toward disciplinary dispersal as digital techniques penetrate the humanities more and more broadly. It is thus difficult to predict whether in 20 years the field will have created very clear boundaries for itself, or on the contrary will simply have become synonymous with "the humanities" and perhaps have disappeared altogether. However, beyond its impact on the practice of traditional humanities disciplines, perhaps the clearest indication of its influence is the emergence of new humanities fields in which digital media are themselves the focus of attention. We have already mentioned new media studies, the study (as Janet

Murray puts it in her introduction to the *New Media Reader*) of “the computer as an expressive medium.” Adjoining this field are two others of note: first, game studies, which takes the same approach but with a close focus on computer games and the expressive logic of the game form. The second is digital aesthetics, not yet perhaps a field but certainly a research domain, again attending to the expressive potential of the digital realm but with an emphasis on specifically aesthetic questions and problems. These three fields which represent visible nodes in an intellectual continuum that is still in the process of coagulating, all take the computer itself, and the digitally networked systems that arise from it and depend on it, as having pervasive cultural significance—not because of their novelty, but because of the distinctiveness of the intervention they are making in our cultural and intellectual habits. The complex relationship between digital information and human cognition, which could be characterized as augmentative, complementary, frictional, or mutually antagonistic seems to reveal problems and questions of deep and lasting significance which we need new tools and approaches to study. Digital humanities may prove to be the durable locus of that study, or it may turn out to be a temporary phase through which these studies are passing on their way to a more tightly defined disciplinary focus.

Digital Humanities and Academic Libraries

Bobby Smiley

Vanderbilt University, Heard Libraries, Nashville, Tennessee, U.S.A.

Michael Rodriguez

Michigan State University Libraries, East Lansing, Michigan, U.S.A.

Abstract

This entry opens by defining and outlining digital humanities as an academic enterprise and exploring the intellectual and institutional connections between digital humanities and libraries. Through an examination of the major publications on the subject, the theory and concepts of digital humanities as a field of inquiry are explored, and how those theories and concepts are possibly mapped to academic library traditional collections and services. The majority of the narrative is then dedicated to focusing on the nature of the work being done in these areas by academic libraries and librarians and the issues and challenges they encounter surfacing in that work.

INTRODUCTION

“[O]f all scholarly pursuits,” the literary scholar Stephen Ramsey relates, “Digital Humanities most clearly represents the spirit that animated the ancient foundations at Alexandria, Pergamum, and Memphis, the great monastic libraries of the Middle Ages, and even the first research libraries of the German Enlightenment.” For Ramsey, digital humanities (DH) “is obsessed with varieties of representation, the organization of knowledge, the technology of communication and dissemination, and the production of useful tools for scholarly inquiry.” These sentiments underline an enduring connection between DH work and librarians, accenting a shared investment in information organization, discovery and access, outreach, and collection development. Indeed, sites of DH research, Ramsey contends, enable “scholars to act more like librarians, and . . . librarians to act more like scholars.”^[1]

Ramsey’s remarks highlight a growing consensus among librarians and DH scholars about the place of the library in DH, and DH in libraries. With expertise in metadata, knowledge of digital collections, and familiarity with the operational side of digital projects—whether sourcing, preparing, and manipulating data; digitization and analysis of text, moving images, or other audiovisual material, information architecture, and user experience; or instruction about tools and techniques—librarians have played an important role in promoting and integrating DH in universities.^[2] At the same time, librarians have also generated DH scholarship, such as leading the large Text Encoding Initiative (TEI), and data and text mining projects, which, inter alia, helps efface and complicate the implied division of labor that often surfaces between librarians and digital humanists.^[3] That librarians are integral participants in conversations about DH as digital humanists is a perspective embraced by many working in the field.^[4]

And while DH labs and centers have been well established and based in libraries (such as the Center for Digital Research in the Humanities at the University of Nebraska), more libraries have begun to investigate different ways of initiating or formalizing their work in DH and are considering the place of the library in the institutional development of DH programs in universities and the attendant difficulties inherent in establishing infrastructure and support for library-led DH initiatives.^[5] But the opportunities offered and the questions raised by this relationship are manifold, and all parties—librarians, professors, and administrators—also understand how indispensable collaboration is in fostering and sustaining successfully digitally oriented research endeavors in the humanities and social sciences.^[6]

This entry opens by defining and outlining DH as an academic enterprise and exploring the intellectual and institutional connections between DH and libraries. The majority of the narrative is dedicated to focusing on the nature of the work being done in these areas by libraries and librarians, by librarians working with academic faculty, and the issues and challenges they encounter surfacing in that work.

DIGITAL HUMANITIES

One of the principal problems for anyone interested in DH is the vexed question of definition. Whether made capacious or narrowly drawn, definitions for DH often reflect the research interests and work of persons proffering definitions. At a talk in 2010, Johanna Drucker, observed in jest that the heterogeneous nature of DH—filled with librarians, information scientists, and scholars working in disparate fields of the humanities—resembled the variegated extraterrestrial crowd at the Mos Eisley Cantina

from the original *Star Wars* film.^[7] And, to be sure, this heterogeneity is reflected in the Whitman's sampler of methodological approaches employed by numerous scholars from the various fields doing original work in the DH: network analysis, algorithmic criticism (topic modeling, word frequency analysis, large-scale text analysis), preparation and analysis of linguistic corpora, digital media archeology, spatial humanities (geo-analysis), data visualization, instructional design and pedagogy, and locating and assembling humanities data sets—to name only a few.

In view of this, when venturing a definition, a more functionalist approach that examines scholarly activities or modalities related to DH is probably most appropriate. For Josh Honn, a Digital Scholarship Librarian at Northwestern University, the work that shapes what is classed as DH falls into five, nonmutually exclusive categories:

1. Scholarship presented in digital form(s)
2. Scholarship enabled by digital methods and tools
3. Scholarship about digital technology and culture
4. Scholarship building and experimenting with digital technology
5. Scholarship critical of its own digitalness^[8]

What Honn means by each speaks (in a disciplinary manner) ecumenically to DH's computational, experimental, cultural, and deeply self-reflexive humanist academic origins. Beginning with Father Roberto Busa's enlistment of IBM in 1949 to help develop the *Index Thomisticus* (often adduced as the first DH project), DH work has been characterized by the engagement of information technology and methods, questions, and content culled from diverse scholarly fields and a concomitant reflection on the use of that technology in that engagement.

By this reckoning, DH is not so much a distinct, intellectually autonomous disciplinary field, but rather as John Unsworth contends, "a method of reasoning."^[9] What this means for librarians is that DH librarianship does not necessarily have to be tethered to the kind of single subject specialization associated with subject librarianship (expressed most frequently by additional disciplinary degrees). Instead, DH furnishes powerful digital tools and interdisciplinary methodologies to gather data, analyze them in ways previously unused/underused in humanities research (for instance, network analysis), and take the results thereof to draw novel conclusions and pose original research questions. This understanding of DH, with its accent on critical, interdisciplinary openness, affords librarians greater purchase, both intellectually and procedurally, in skilling up for, participating in, or overseeing DH enterprises—whether as extensions of library-focused work (using DH methods for collections analysis), as collaborations with disciplinary faculty (procuring data for research), or building digital projects.

LIBRARIES AND DH: THEORY AND PRACTICE

Theory

The current scholarship on DH and libraries theoretically and conceptually places libraries within the DH more as collaborative entities and having a greater role in faculty scholarship endeavors. As the title of the 2015 Association of College and Research Libraries (ACRL) publication *Digital Humanities in the Library: Challenges and Opportunities for Subject Specialists* suggests, DH and libraries has now in great part wrested with subject librarians and collections specialists. In collaboration with other campus entities (mainly faculty, but also grad students), libraries and librarians can offer "partner relationships, becoming embedded in the mission-critical aspects of higher education—research, teaching, and learning—and infusing librarians particular expertise, collections and values into new types of research. . ." (Forward, X).^[10] This ACRL publication does well to combine many of the "core" publications on libraries and DH that came before it—especially Issue 53 of the *Journal of Library Administration*, the Association of Research Libraries (ARL) SPEC Kit 326, and the Ithaka report on *Sustaining the Digital Humanities: Host Institution Support Beyond the Start-Up Phase*—by giving an overview of the state of scholarship in the field as pertains to libraries, while simultaneously demonstrating best-case scenarios and real-world solutions to DH-generated problems. Most recently, *Laying the Foundation: Digital Humanities in Academic Libraries* does well illustrating how "librarians are critical partners in DH instruction and inquiry and that libraries are essential for publishing, preserving, and making accessible digital scholarship" (xii). Along the 2016 SPEC Kit 350 on *Supporting Digital Scholarship*, these publications (among many others) form a core of titles around which to explore three areas of theoretical encounters: 1) how libraries enact and engage DH, 2) how libraries understand and relate to DH, and 3) how libraries can sustain, foster, and facilitate DH.

How libraries enact and engage DH

The first to appear of the "core" publications on the subject was the 2011 ARL SPEC Kit 326: *Digital Humanities*, which was made to answer the question of whether and which libraries offered centers or services that support DH work. Its stated purpose was "to provide a snapshot of research library experiences in these centers. . . and the benefits and challenges of hosting them" (p. 10). By way of survey, the SPEC Kit identifies major trends of libraries supporting DH and estimates levels of project staffing, services and support, hardware and software, (the range of) service users, actual project workspace, funding sources, policies and procedures, sustainability (through project preservation), partnerships, and whether these

efforts were undergoing assessment. The survey recognizes the relative prevalence of “bricks and mortar” DH centers (as opposed to a more general digital scholarship center) and how great the overall effort of a library team (with other units such as metadata and preservation units) being involved is. The remainder of the SPEC Kit delineates findings from the survey instrument, and then provides representative documents (mostly screen captures) attached to the DH-related units who responded. Especially useful are the conclusions that libraries are most useful (and are considered that way by scholars) at the starting and ending phases of a DH project because they provide knowledge of various information technologies and collections, and because libraries have knowledge of metadata and preservation.

In 2016, ACRL released another SPEC Kit (350) on *Supporting Digital Scholarship* that surveyed and updated much of the same terrain as the earlier publication. That these volumes bore a remarkable similarity in content yet were branded differently could serve an informal index of how ACRL envisions how libraries enact and engage DH. Using Abby Smith Rumsey’s definition for digital scholarship, this SPEC Kit understands library engagement as the “use of digital evidence and method, digital authoring, digital publishing, digital curation and preservation, and digital use and reuse of scholarship.”^[11] For librarians, what this engagement includes are varied activities and support services within the library, such as digitizing and reformatting analog media, metadata creation, building digital collections and exhibits, digital publishing support, database support, software development, interface design, and consulting on geospatial information (GIS) and digital mapping projects, doing text encoding and analysis. Indeed, the move toward “digital scholarship” elicits questions about what, if anything, is distinctive about “digital humanities” librarianship. *Supporting Digital Scholarship* does not discuss or acknowledge a distinction (nor does it use “digital humanities” in its executive summary). Given the list of duties detailed in the report, an emphasis on generating original scholarship, or acting as research partners, is comparatively not stressed.^[12] Whatever “digital scholarship” is for libraries engaging in DH, it remains undetermined whether the term functions as simply rebranding, implies a discrete set of duties that principally accent service and support, or extends librarians’ work in DH to other disciplines as library-led scholarship.

How libraries understand and relate to DH

In 2013, the *Journal of Library Administration* devoted an entire issue to addressing the nexus of DH and libraries—what was currently being done and what the future was. Chris Alen Sula’s article on *Digital Humanities and Libraries: A Conceptual Model* for the first time presents

a “cultural informatics model of libraries and digital humanities, and (situates) DH work with the user-centered paradigm of library and information science.”^[13] By doing so, Sula conjoins DH and libraries and how the two can be operationalized through collaboration—both within the library (between library units) and across campus. This model places emphasis on relevancy rather than sustainability, which is a slight departure from the scholarship on the subject previously. Potential collaboration between DH scholars and librarians then “offer(s) an important opportunity to provide renewed support for the humanities and to bring library resources across the board up to speed with digital scholarship for the 21st century.” Others within the *JAL* issue pick up the mantle of collaboration: Jennifer Vinopal and Monica McComick suggest that “New models for librarian-scholar collaboration include much more librarian engagement with the entire research process than ever before,” including “grant-seeking, project planning, data collection and organization, and metadata creation,” as well as “data analysis and visualization, content dissemination, and long-term archiving.”^[14] And this range of work is reflected in the multi-institution survey results from librarians reporting about the variety of work they do published the 2016 ACRL SPEC Kit on digital scholarship:

- (90–95%) making digital collections, creating metadata, and offering data curation and management support
- (85%) creating exhibits and project planning
- (81%) GIS and digital mapping
- (79%) digitization
- (76%) digital publishing
- (72%) project management
- (38%) developing DS software^[12]

How libraries can sustain, foster, and facilitate DH

The Ithaka report on *Sustaining the Digital Humanities: Host Institution Support Beyond the Start-Up Phase* combines the theoretical with the practical, demonstrates what libraries are doing with DH, and points out possible success scenarios for the future—in part answering the mythic question of “If I/we build it will they come?”^[15] Though the study focused on a small but tidy group of ARL institutions that had established DH “centers” within their libraries, many other administrators, librarians, and scholars were interviewed around questions having to do with sustainability, investment in resources, and expected outcomes. For libraries, the report is important for its insistence on institutional (“top level”) support from university administrations and provides several frameworks for gap analysis surveys to be done on campuses. Once it has been decided upon whether to start a DH center, and the answer is “to build,” then there is a practical road map

in the section on “Success Factors and Examples of Good Practice” by keeping the following in mind while visualizing and operationalizing a DH center:

1. Knit deep partnerships among campus units (library, IT, digital labs).
2. Rationalize support and manage faculty expectations.
3. Figure out how to use scale solutions, without overly limiting the creativity and research aims of project leaders.
4. Clearly communicate pathways and expectations to faculty.
5. Measure and communicate impact.

The report goes beyond previous theoretical models and suggests the “Comprehensive System” for creating the DH center through

1. A clear starting point for any faculty or staff developing digital projects
2. An “intake” process that allows an important screening process
3. Regular communication among those units on campus with human or infrastructure capacity to share
4. Establishment of measures for success
5. Bring(ing) in new partners to the digital life cycle to support dissemination activities
6. Documentation that spells out the process to all faculty and staff members

The Ithaka report is heavy on institutional collaboration for the success of a DH unit, as are most of the advisory takeaways from the scholarship on the subject. So in answer to the question “If I/We build it will they come?” the answer is, “Only if you build it in partnerships and collaboration with other campus entities.”

The subtext of the Ithaka report also suggests an emphasis on new skills and ways approaching the profession for librarians of the twenty-first century. Preceding Ithaka was a 2012 report released by Research Libraries United Kingdom (RLUK) that broadly redefined roles for subject librarians.^[16] Entitled *Re-skilling for Research*, the report accented the growing importance of equipping academic and research librarians with a large swath of technical skills associated with data analysis and curation, in addition to further training in grant writing and soliciting funding for projects. The recommendations in *Re-skilling* for subject and liaison librarians in academic and research institutions conclude by emphasizing how these librarians have effectively created and curated metadata in the past, and will be required to do more of the same in the future.^[16] Librarians must evince “knowledge to advocate, and advise on, the use of metadata,” as well as possess “[s]kills to develop metadata schema, and advise on discipline/subject standards and practices, for individual research projects.” This emphasis on training is also

outlined by Alix Keener in her study of DH scholars and academic librarians within the Center for Institutional Cooperation (CIC) network of institutions, where she urges “libraries . . . [to] address internal issues, such as training and re-skilling librarians as necessary,” in order to help “make the library an active and equal partner in research.”^[17]

Practice

Owing to its relative, more formalized newness in libraries, steps for practical implementation of library-led DH initiatives have only recently begun to be discussed. As a template based on their own experiences, Katie Gibson, Marcus Ladd, and Jenny Presnell have outlined a tiered commitment level description of how librarians can start building DH capacity through outreach, instruction, and self-education:

- *Low commitment*: connect with graduate students, explore other DH sites and projects, and learn about institutional technological infrastructure, preservation formats and standards, and altmetrics.
- *Moderate commitment*: host DH symposium with external participants, collaborate on designing curriculum for courses, provide workshops, and seek opportunities to learn DH tools and how to code.
- *Intensive commitment*: build new DH projects with materials sourced from library’s unique holdings.^[18]

As indicated, skilling up for DH work (learning code, tools, methodologies, data manipulation, different application programming interfaces [APIs]) composes an essential component at all stages, and beyond self-paced websites (e.g., Codecademy) or MOOCs, options are limited for professional development—and are often pitched to those already working in allied, tech-heavy areas. Some institutions have developed in-house initiatives designed to equip subject librarians the “hard” technological skills often needed for DH projects. For instance, informed by *Re-skilling for Research*’s conclusions about the future import of DH, the humanities and history librarians at Columbia University formed the Developing Librarian Project, a 2 yr hands-on effort to learn-by-doing that required them to design and build a digital project ab initio. But, explains Miriam Posner, the coordinator and core faculty in Digital Humanities Program at the University of California, Los Angeles, “much of the discussion about building a DH-friendly library environment leans too hard on individual librarians, without taking into account the set of institutional supports, incentives, and rewards that will allow DH to flourish in a sustained way.”^[19] In addition to these concerns, Posner emphasizes several practical problems library-based DH work can encounter, and ones that might stymie any level of commitment investment; these include limited training

opportunities, “lack of support for librarian-conceived initiatives,” innumerable tasks with limited time, “lack of authority to marshal the appropriate resources,” “inflexible infrastructure,” “lack of incentive,” concerns working with faculty, “diffusion of effort,” and “lack of a real institutional commitment.” By drawing attention to these issues, Posner urges consideration not only of the substance of DH library work but also how necessary the material conditions and institutional commitments are to enable and sustain its possibility.

For librarians just beginning to establish or build out DH work in the library, more sensitive, existential, and political questions surface concerning their role in that work. If there are librarians doing DH work, asks Dot Porter, the curator for Digital Research Services at the University of Pennsylvania, then “what the heck is a DH academic?”^[20] In high-level discussions of DH in the library, there is often an implied division invoked between “librarians” and “DH scholars/academics” and an argument for understanding the role of “librarians as digital sherpas” or for separating out the work of the “DH skilled-librarians” from “DH academics.”^[21] And, to be sure, such a perspective is in consonant with the traditional service orientation of library work, which accents librarians’ role in providing critical and often necessary support and guidance for DH projects. Without library expertise, for instance, in furnishing metadata or sourcing data sets, DH projects that rely on these indispensable library services would most likely flounder or stall. But as Alix Keener explains, while “scholars appreciate the specialized expertise of librarians” (such as metadata and special collections work), librarians at the same time should “take a more active stance in utilizing current library resources or vocalizing their needs for other resources.”^[17]

All the same, as Trevor Muñoz, assistant dean for Digital Humanities Research at the University of Maryland Libraries, contends, “[d]igital humanities in libraries isn’t a service and libraries will be more successful at generating engagement with digital humanities if they focus on helping librarians lead their own DH initiatives and projects.”^[4] While these two approaches are not mutually exclusive, they do suggest the charged valence that often slots digital humanists working in the library into a category that is distinct from colleagues stationed in other campus units. “It doesn’t make sense to measure the digital humanist-ness of someone,” Porter advances, “based on their current post (especially as digital humanists tend to be fairly fluid, moving between posts inside and outside of the library).” And to militate against these concerns, Bethany Nowvickie, director of the Digital Library Federation and director of Digital Research and Scholarship at the University of Virginia Library, proposes embracing a collaborative model that emphasizes independence and parity, the “Skunk Works.” Taken from a Lockheed-Martin working group, the term skunk works “describes a small and nimble technical team, deliberately and self-

consciously and (yes) quite unfairly freed from much of the surrounding bureaucracy of the larger organization in which it finds itself.”^[22] For building DH projects that involve participants across university units (including the library), skunk works are premised on marking out inventive spaces for digital humanists—irrespective of job title—to collaborate as research and development peers in generating original research. As Harriet Green argues, only by “engaging in radical collaborations and pursuing new reconfigurations of library engagement and services, librarians can become even more embedded in the research workflow and engage researchers as partners.”^[23]

With these practical—and at times abstract—considerations informing the library environment for DH work, the operational side for the library resembles the recommendations of the tiered commitment model outlined by Gibson, Ladd, and Presnell. Working from those recommendations and expanding its scope, a more generic set of terms to group the elements described can be divined that characterizes the broad areas of work DH librarians do: instruction, consultation and collaboration, and collection. While many librarians do work in these areas (in the case of the subject specialists, usually all four), these terms take on a special, practically oriented valence when used in a DH context.

Instruction

For many librarians, instruction often entails teaching information literacy, or providing demonstrations of print and electronic resources or discovery systems, like the library catalog. While this variety of teaching falls within the purview of librarians whose work might encompass DH, instruction for DH librarians frequently emphasizes two ways that extend traditional library teaching: pedagogical collaboration with teaching faculty and leading workshops and boot camps.^[24] Ideally, informing instruction in these settings is a holistic understanding of digital pedagogy that helps facilitate digital literacy, that is, as Anita Say Chan and Harriet Green explain, these are pedagogical approaches that “connect digital tools to research practices linked to course content.”^[25]

Library-led curriculum support in DH can range from working with instructors to developing assignments that introduce DH tools and methods, making available data sets for analysis (whether sourced from the library’s own collection or available elsewhere), or leading sessions that introduce tools or being an embedded presence providing specific assistance for DH class projects. Successful pedagogical collaborations between librarians and teaching faculty, Zoe Borovsky and Elizabeth McAulay argue, usually involve making “subject matter . . . the central concern of the course rather than digital methodology.”^[26] In other words, these collaborations can help cultivate digital literacy (for instance, evaluating different digital tools and methods) from grounding in and speaking

through disciplinary knowledge. Another common area of instruction for DH librarians are workshops or boot camps, which pivot around introducing DH tools and methods in a manner often similar to information literacy sessions, albeit without the disciplinary focus. There are efforts to explore to use the unique affordances of library instruction to teach DH through information and data literacy principles, as well as disciplinary expectations, but much of the teaching remains tool focused.^[27] Whether course based or workshop introduced, Adeline Koh has identified four general types of projects best suited to library-led DH instruction: digital mapping, text analysis, multimedia websites/online exhibits, and Wikipedia editing.^[28] These types of projects can both complement disciplinary instruction as well as serve as a single session in a workshops series. In all instances, library-led DH instruction incorporates traditional elements of library pedagogy (information literacy, one-shot sessions) but entails greater collaboration and co-presence with teaching faculty.

Consultation and collaboration

Like instruction, consultation for DH librarians builds upon the principles of the reference interview and an understanding of information seeking behavior but is also frequently augmented by counsel, partnership/collaboration on grant writing, research data management, technical advice, and project management. With its stress on collaboration, DH consultations in the library can (or in some cases are designed to) become equal partnerships on projects or initiatives. Elizabeth Lorang and Kathleen A. Johnson particularize elements that can be read as project consultation that evolves into (or is in its conception) a successful DH collaboration.^[29] Their inventory of requirements includes articulating clearly the project's research question and the scholarly conversation being entered, researching other projects with similar research aims or methodologies, defining the scope of the project, developing a communication plan, investigating issues regarding intellectual property, developing a project work plan and a data management plan, providing regular assessment of project development, and documenting project work (among several others).

Much has already been discussed here about collaboration—both as intralibrary initiatives that take advantage of existing collections and services and also between faculty and librarians. Collaboration between faculty and librarians arises in part because of a fundamental shift in the world of academic publishing, which has made academics turn to libraries as partners in their endeavors. Open-access publishing has created new methods of disseminating scholarship, and libraries have now found themselves in the middle of this new and challenging landscape, at least in part due to the rise of institutional repositories (which are often administered by academic libraries).

Many institutions have mandated open-access scholarship and simultaneously mandated that libraries become repositories for data and the publications that arise from research. A “Research Data Management Plan” became mandatory for the National Institutes of Science Education and Research grants in 2013 and the mandate became a requirement for the National Endowment for the Humanities shortly thereafter, which was important for those doing DH projects. When scholars turned to libraries for help with managing, housing, and providing access to data, and even with publishing research, the open-access movement began to take shape within libraries. So we must now add to the role of an academic library (in addition to the traditional roles of acquisition, organization, and preservation of information) the roles of curation and publishing. This is significant to DH practitioners when they realize that libraries have long been the curators and preservationists for digital collections, understand digital publishing issues, and serve as natural collaborators for DH projects. In addition to the roles of acquiring, curating, and disseminating DH projects, subject librarians can also be the natural collaborating partners for the teaching of workshops and instruction sessions for combining digital collections with the DH project management (see the *Instruction* part of this article). The list of DH projects that have academic libraries as their center abound: ARC (NINES, 18th Connect, MESA, and others, now centered at Texas A&M: <http://idhmc.tamu.edu/arcgrant/>), the Text Creation Partnership (centered at the University of Michigan: <http://www.textcreationpartnership.org/tcp-texts/>), to name but a few.

Collections

Traditional collection management responsibilities, such as purchasing monographs or databases, building subject-specific collection strength, or even negotiating with vendors, are situated in an expanded field when considering DH in a library context. Evaluating what constitutes of the components of what is collected, what formats—or how many, and how they are made accessible, uniquely DH collection practices are broadened to include to what can be termed, in this context, humanities data, whether these data are textual or audiovisual, but always in a digital form. Like traditional collection management, the way in which these data are accessed, stored, and made discoverable are paramount questions, but they are also ones made more complicated when curating with born-digital materials.

For Miriam Posner, the idea of humanities data is “a necessary contradiction.”^[30] Indeed, humanities scholars often find it difficult to reimagine books, photographs, and film, among other formats (including born-digital ones, like websites), as agglomerations of discrete data points. But when rendered digitally (or already digital), the possibilities of analysis at scale, or working with metadata

about a text (whether descriptive, technical, or administrative metadata), are opened in ways not previously countenanced. With this in mind, Devin Higgins and Thomas Padilla define humanities data as “organized difference presented in a form amenable to computation [and] put into the service of humanistic inquiry.”^[31] For instance, a scholar could use the API of the Digital Public Library of America to retrieve, en masse, a subset of bibliographic metadata in JSON for a distant reading project. The metadata harvested and transformed constitute humanities data sets, drawn from a larger universe of humanities data, and formatted for computational analysis. Because of its unique affordances, that humanities data are available digitally is what enables novel forms of analysis.

Humanities data, like research data or other data available digitally, requires curation. Julia Flanders and Trevor Muñoz describe the principal purpose of humanities data curation as “ensur[ing] that the representations of objects of study in the humanities functions effectively as data.”^[32] What they mean by this is that humanities data curation maintains data for computational analysis and keeps it interoperable across systems and format migration “while still retaining provenance and complex layers of meaning.” Often questions of curation fall outside the ambit of collections, but recognizing humanities data unique characteristics, such as the features of scholarly editions, text with markup (like TEI), textual corpora (and the fonds thereof), or other annotated data accompanying analysis, can afford a better perspective on how these data are collected and used.

For libraries, the challenges of working with humanities data can be complex. While there are manifold online repositories (the Internet Archive and HathiTrust, among many others), the rationale for libraries to collect one variety of humanities data over another can be a confusing proposition. In many instances, humanities data are digital versions of analog material (and by being rendered digital are thus freighted with additional metadata in order to be made available for the possibility of computational analysis), and this can generate concerns about collection duplication, and item reproduction. If an item is made available in one digital format, is there argument it should be available in another? And, if so, what copyright issues will need to be addressed in producing an additional digital access copy for computational analysis? For librarians thinking about DH in their collection management decisions, addressing the unique affordances of humanities data will be an intellectual and operational challenge, but a necessary one for fostering DH scholarship at their institutions.

CONCLUSION

“Libraries and digital humanities have the same goals. Stop asking if the library has a role, or what it is, and start

getting involved in digital projects that are already happening. Advocate for new expanded roles and responsibilities to be able to do this. Become producers/creators in collaboration with scholars rather than servants to them.”

In his article from *In the Library With a Lead Pipe*, Micah Vandergrift, echoing Matthew Kirschenbaum’s “What Is Digital Humanities and What’s it Doing in English Departments,” gets to the point quickly that DH is something that libraries have in a less unified form been doing for quite some time, though they may have been calling it something else (digitization projects, metadata, curation of digital projects, etc.).^[33] Libraries that have actually named DH units in order to keep up with the prevailing parlance of academia are reimagining already existing services and collections, leveraging their knowledge of metadata and familiarity with digital project management, while adding to that existing knowledge and resource base the sourcing, preparing, and manipulation of data, and analysis of digitized text, image, and audio for both themselves as a campus unit and for the patrons they serve. Most of these DH units are based around the following areas: collections (to build and/or enhance collections amenable to computational analysis, enable new modes of discovery and access to collections, acquire and/or condition data to support pursuit of DH research questions), collaboration (to partner on DH research, develop tools, convene events, symposia, and colloquia), consultation (to aid with text analysis, network analysis, image analysis, visualization, digital preservation, data curation, grant application process), and instruction (in method, tool, and technique lectures and workshops). As libraries reskill and transition to new ways of supporting patron teaching and research, they also find themselves in new roles because of the changing landscape of academic publishing—and because of repositories, librarians find themselves at the nexus of curation, consultation, and collaboration in the publication of research. So whether or not scholars agree on what DH means and what forms it takes (or should take), the practice of DH looks to remain core to the mission of academic libraries well into the future.

Digital Images

Melissa Terras

UCL Department of Information Studies, UCL Centre for Digital Humanities, University College London, London, U.K.

Abstract

Although the technologies that underpin digital imaging have been in development for a surprisingly long time, recent developments in computing and networking technologies mean that digital images have recently become the dominant means to create and share photographic material. The Library and Archive sector were early adopters of these technologies, with many and various digitization projects being undertaken to produce digital images of important holdings, which is now an expected practice across the heritage sector. Best practice guidelines have been produced to provide technical and managerial recommendations for those wishing to undertake digitization projects. However, due to the increase in digital images in general society, the information professional also has role in educating industry and the public regarding issues in the long-term preservation of this medium, and we are now at a juncture where cultural and heritage institutions have to explore how best to interact with the general public effectively via digital images.

INTRODUCTION

Images are an integral part of human history, culture, and society. From daubing on rocks, to inventing printing and photographic techniques, humans have continually improved the technology available that enables them to create, share, and disseminate visual information. The way we produce, manipulate, disseminate, and comment on visual imagery has changed considerably since the closing parts of the last millennium. Recent developments in digital imaging, personal computing, and networking technologies have led to an exponential increase in image-based material, from both the personal and public sectors. Digital images are now the dominant, and pervasive, medium used to create, display, and share photographic images, and photographic reproductions of objects and artifacts. The library, archive, museum, and cultural sector were quick to embrace these technologies to increase access to collections through digitization: creating digital representations, usually images, of holdings, predominantly for distribution via the Internet. Various guidelines and recommendations are now in place to ensure best practice in creating digital image surrogates for memory institutions, although concerns regarding benchmarking, quality, management, and long-term preservation remain. Questions regarding use and usefulness are also being raised: does the evidence of use match the investment required to create such representations? Additionally, the pervasive use of digital imaging technology by the general public presents novel and immediate concerns for information professionals.

THE HISTORY OF DIGITAL IMAGES

Visual imagery is a powerful communicator, and the development of digital imaging technologies is tied to the development of communications technology, itself dependent on complex relationships between various scientific discoveries and the culture that encouraged them. Digital photography did not just materialize in the late twentieth century: scientists and technologists had been working for over a hundred years to understand how to use the power of electricity to communicate across long distances and how to use automated computational power to carry out mathematical analysis, eventually finding ways of capturing, distributing, then storing and processing digital information, including images. In turn, the growth in information communications technologies has led to the increased production and use of digital images in all areas of life and culture in the developed world.

Shortly after the first telegraph message was sent in 1837 (2 years before the “discovery” of photography), inventors aimed to transmit drawings via this new technology, with a working system in operation by 1851.^[1] By the mid-1860s, the Victorian world possessed the understanding and the means to enable an image to be scanned in, distributed, and reproduced electronically, in a precursor to facsimile, or fax, technology. Photographic images were first sent by fax in the 1890s, and by the late 1900s, with the discovery of silicon’s conductive properties, technological advances meant automated light-sensitive scanning was available. By using such optical technology to analyze an image broken up into discreet sections, or pixels, and by sending these encoded signals over the

wire, digital scanning, encoding, and reproduction of photographs was possible. This was established in 1920 with the Bartlane system, named after its British inventors, H. G. Bartholomew and M. L. MacFarlane. Many early transatlantic news images appeared in newspapers after being delivered via this system, cutting down transmission time from a week (the time it took a ship to cross from the United States to the United Kingdom) to a couple of hours. By the 1930s, the transmission of images by digital fax was commonplace, with many commercial news organizations owning scanners and networks throughout the world, yet although the digital fax converted images into digital signals by breaking them into refined units, and expressing these units numerically, it was missing vital elements of image processing and electronic storage: digital representations could be created, distributed, then printed, but computing technologies did not yet exist to store or manipulate them.

It was over 35 years later that computers could be powerful enough to store or manipulate digital image representations: in 1957, a drum scanner was used to input image data into a SEAC 1500 word memory computer.^[2] Advances in computing and digital imaging technologies were many and varied in the Cold War years (NASA invested large sums to investigate the use of digital image technologies as a means of defense). However, it was not until the 1980s when the falling costs of computer components, and rising storage and processing capacities of computers, meant that access to computational power became more commonplace, allowing (and requiring) research and development to be carried out on the intricacies of picture-generating software and systems. By the close of the twentieth century, most basic, affordable personal computing systems were able to handle standard full-color images and were capable of running sophisticated photo-manipulation software that allowed digital manipulation that rivaled the accuracy and resolution of traditional photographic darkrooms.^[3] Image capture peripheral devices also became increasingly available (scanners, digital cameras, mobile phones incorporating digital camera technology, printers) in cheaper and smaller incarnations, encouraging users to abandon traditional film-based photographic technology.

Alongside these developments, engineers and computer scientists were also busy constructing networks that would allow computers to source and exchange information. The Internet, and its subset, the World Wide Web, is the perfect vehicle for the distribution of both professional and user-created digital content: having a reliable, and fast, networked environment that can act as a way to share, disseminate, and view digital information has encouraged the creation of both digital versions of analogue material (through digitization) and digital-born media. The role of the Internet in encouraging the uptake of digital image technology should not be underestimated, and digital images of artifacts, objects, people, and places are often

the central focus of information available online. Various online communities now exist around image-sharing sites, including the photo-sharing site Flickr.com, the lifestyle imagery site Pinterest.com, the photo-sharing and -filtering site Instagram.com, and the image-based blog site Tumblr.com.

The history of digital imaging is rooted in the Victorian era but was only toward the end of the twentieth century that it has existed as a practical technology, due to converging developments in communications technology and the networked environment, increased access to cheaper and faster computers, and the lowering cost and improving performance of the peripherals that create digital images, all encouraging the production and use of digital images, by both individuals and institutions. This has been followed by a corresponding rise in user expectations regarding the quality and amount of digital image information that should be able to be produced by desktop machines, or be available online. The recent rapid uptake of digital imaging, and the growing provision of services and online tools, means it appears to be, and functions as, a new medium, changing the information environment and creating new concerns for those working in the information professions.

DIGITAL IMAGE FUNDAMENTALS

There are two distinct classes of digital images: vector graphics (which use a series of geometric drawing commands, such as lines, curves, or shapes and solid or graduated color, to represent an image), and bitmap or raster images (where an image is broken into a grid by the capture device, with the light value (lightness, darkness or color) of each piece of the grid—an individual pixel—recorded individually. The term *raster* stems from the Latin, to rake). Bitmaps are relatively easy to implement, and, within limits, work for any image: they can record just about any conceivable image or view of a scene since any image can be broken up into a grid, and as far as the human eye is concerned, if that grid is small enough we see it as a continuous tone image. Vector graphics are predominantly used in graphic design, and computer-aided design systems for engineering and architecture: neither bitmap or vector graphics methods are better than the other: they simply have different functions and uses. Digitization projects and cultural and heritage institutions will be most likely to produce and deal with bitmapped images, although as Digital Humanities techniques become more widespread, images are also increasingly used alongside other types and formats of data such as marked up text, large textual repositories, or geographically encoded data (see Schreibman et al.^[4] for an overview of different commonly used approaches to information generated from the digitization process).

The term “pixel” has been used to describe the individual points of a bitmapped image since the 1960s, being an

abbreviated form of “picture element.” Each pixel contains complete information about a particular point of an image, detailing the color (hue, lightness, and saturation) and place of the individual pixel within the grid. From a mathematical point of view, this array is merely a collection of numbers that may be transformed and manipulated in a wide variety of ways. Such an array is called a *bitmap*—a representation of the image data that parallels the manner in which it is stored in computer memory. Bitmap image pixels are generally square, but pixel size is variable depending on the size of the grid chosen to display or output them. The number of pixels in a given area is described as the *resolution* of the image. The amount of color information stored for each individual pixel is determined by *bit depth* (Fig. 1).

Resolution is usually denoted by a measurement such as pixels, or points per inch (ppi: measuring the number of pixels in an image within a linear one-inch space), dots per inch (dpi: measuring the number of individual dots of ink a printer can produce), or lines per inch (lpi: used to denote how close together lines are in halftone printing, the method commonly used in newspapers and magazines where images are represented by a series of dots of different size and density). The terms are often used interchangeably when talking about image resolution, dpi being the most common, and conventionally understood to cover different media. (For cameras, resolution is stated differently. Rather than the number of pixels in an inch, the resolution given is usually the maximum resolution a digital sensor at the back of the camera can achieve, normally expressed as the absolute number of pixels in the grid, rounded up to one decimal place.) The topic of resolution can be confusing because it isn’t fixed and immutable. If you change the size of a digital image without changing the number of pixels within it, you change its resolution: the size of the grid has changed without changing the individual elements within it. Interpolation—the term given to the mathematical creation of missing data—is often used to create new pixels to insert into, or choose which pixels to delete from, a resized image, in order to maintain image resolution and to ensure that the image does not become visibly disrupted, or pixelated. The ideal resolution at which to capture or store an image depends on the purpose of the image: resolution for online display, for example, is much lower than that needed for print or archival purposes. Digitization guidelines (see section “Use of Digital Images in the Library and Archive Sector”) provide guidance in this area (Fig. 2).

Bit depth describes the number of bits of memory that are available to describe the color of each pixel of the image. The greater number of bits assigned to each pixel, the greater number of colors the image can have. The simplest type of image, black and white, sometimes referred to as a binary image, has a bit depth of 1, as each pixel is either black or white (0 or 1). Grayscale images are 8 bit—capable of describing 256 difference shades of gray.

Fig. 1 A digital image of a Mediaeval stained glass window. At the viewing resolution, pixels cannot normally be seen, but when magnified, such as the lower section featuring the devil’s eye, the underlying matrix containing pixels of individual color become apparent. Being able to see pixels within an image under normal viewing conditions is termed “pixelation.”

24-bit and 32-bit colors are capable of describing millions of different permutations of color information for each pixel. 48-bit color is capable of describing billions of different colors (more than the human eye can discern, and only used for specialist systems). The amount of color information created, sampled, or stored regarding an image depends on the image’s purpose: for some images, such as representations of black and white newspapers, color brings little to the image, whereas for others, such as images of mediaeval manuscripts, color may hold intrinsic information regarding the object. Digitization guidelines provide guidance regarding the bit depth suitable for different media (Fig. 3).

Fig. 2 A section of an image of a Mediaeval stained glass window captured at different resolutions. (A) At 30 pixels per inch, the size of the pixels is above the threshold of human vision, and the image is pixelated. (B) At 72 dots per inch, the image is suitable for online display, and we see it as a continuous tone image, but some detail is lacking. (C) At 300 dots per inch, the level of detail captured makes the image a more accurate representation of the object.

Creating accurate representations of objects and artifacts using digital imaging technologies requires attention to detail: photographing objects at high resolution and normally, now, at full color (over the past few years, the sector has moved away from scanning, and black and white capture, as Digital SLR cameras and the cost of data storage have come down in cost). However, the more samples captured, and the more detailed the color information captured, the larger the file size of a resulting digital image. There is a payoff between representing detail and the ability to manipulate, display, and disseminate images efficiently. Smaller file sizes are required, for example, for delivery via the Internet. Compression techniques are often used to reduce the number of bytes

required to represent a data set: some techniques are designed to store information efficiently, while others store the data set accurately. Lossless compression ensures that an image viewed and decompressed will be identical to its state before being compressed (but although the image is stored accurately, it is difficult to reduce the file size significantly using lossless compression). Lossy techniques eliminate information from the pre-compressed state, the amount of detail discarded can usually be adjusted to change as little of the visible detail in an image as possible. Lossy compression can achieve significant storage savings and is ideal for creating images for display on the Internet; however, once the information is gone, the original image cannot be recreated. It is important to use lossless

Fig. 3 A section of an image of a Mediaeval stained glass window captured at different bit depth. The top section is bitonal, being only black and white, and although the resulting file size is small, much of the detail is lost. The middle section demonstrates the same image section in grayscale: 256 different shades of gray, which is much more effective in capturing detail. The final section, in 24-bit color, contains much more information, demonstrating that the provision of color information can be important when providing images of originals that rely on vivid color themselves.

compression for images that are to be stored long term, such as master files resulting from digitization projects, to ensure that all information possible is preserved for future use.

Further information and introductions to the basic infrastructure of digital images specifically targeted for librarians and information professionals are available,^[5–10] with many digitization projects using the Library of Congress “Technical Standards for Digital Conversion of Text and Graphic Materials” as a base.^[11] The Jisc Digital Media service (formerly the Technical Advisory Service for Images) provides many up-to-date online guides to digital imaging at <http://www.jiscdigitalmedia.ac.uk/>. A detailed introduction to the fundamental physics, mathematics, and perceptual phenomena behind digital images, covering optics, electronics, photography, and semiconductor technology is also available.^[12]

IMAGE FILE FORMATS

Image formats are files that store any type of persistent graphical data (as opposed to text, spreadsheet, or numerical information) that is intended for eventual rendering and display. There are now over one hundred image formats in existence^[13] and that number continues to grow: different applications use different types of data in different ways to satisfy different user needs. A cultural and heritage digitization project will mostly work on creating two-dimensional representations of artifacts and documents, or bitmap graphics, and use commonly available formats to facilitate interoperability and information exchange of digital image data. Using recommended, commonly available, documented formats also ensures that the information should be accessible when technology advances, and formats change and become obsolete. File formats can be converted from one to another. This can be useful if the organization of the data stream is incompatible with the requirements of a particular device or application, or if the original format is not one suited for, say, online delivery, long-term storage, or interoperability.

Although there are many different image file formats, most work in a broadly similar way. Most typical data sets consist of a linear list of data values, commonly referred to as a data stream. The entire data stream makes up the file. The difference between individual image files formats lies in the details: what type of data is stored, if it is compressed, and how it is encoded. A typical structure of an image data stream may be: File Signature (declaring which format the data are stored in), Image Header (containing technical information that describes the image, such as pixel dimensions, image height and width, and bit depth), perhaps a Color Palette (a means of storing color information effectively), then the individual pixel color data (the major part of a data stream for a bitmapped

image, storing individual pixel color values, usually in display order: this is the part of the file that can be compressed), and finally a File Closing Marker (marking the end of the data stream, and so the end of the file). Disruption to this datastream generally means that the file cannot be read at all.

The most popular image formats that an information professional may come across are GIF, PNG, JPEG, and TIFF. GIF, PNG, and JPEG files are commonly used to save images that need to be compressed in order to be delivered easily across a network, such as the Internet. GIF files have a limited color palette and use a compression algorithm that is suited to compressing areas of the same color, meaning they are suitable for logos, graphics, and buttons. The PNG format is becoming more popular for this purpose: it was designed to improve the GIF specification and to avoid any of the licensing issues that plagued GIF toward the close of the last century. JPEG is actually a method of file compression specifically designed to cope with complexity of photographic images, and the file format developed to incorporate this technique is now the most common format for storage and interchange of digital photographs, although it is a very lossy format. TIFF files are one of the most useful formats for the capture, storage, and exchange of high-quality digital image data. Since the early 1990s, TIFF has been embraced as an archival digital image format by the library and archive community and is now also in common use as an output format from professional-level digital cameras. It is recommended that the capture of archival and library material is done “once for all purposes”: creating a high-resolution TIFF file of an object will allow lower resolution and compressed image files in different formats to be generated from the master file, while creating a digital surrogate for long-term preservation and access, and limiting the handling of the object experiences.^[14] However, many digitization studios are now also maintaining the RAW files that come directly from a Digital SLR sensor, allowing further tonal adjustments at a later stage, although these can be very large. In addition, there is a growing interest in the JPEG2000 format, which allows more sophisticated image compression and storage possibilities than either existing JPEG or TIFF. Again, digitization guidelines can provide guidance in this area, and the recommendations and documentation on a working group on the use of JPEG2000 in the heritage sector are also available at <http://wiki.opf-labs.org/display/JP2/Home>.

USE OF DIGITAL IMAGES IN THE LIBRARY AND ARCHIVE SECTOR

The Information, Culture, and Heritage sectors were quick to embrace the potential of imaging technologies as they became available, primarily to facilitate access to items in collections by providing them in electronic format,

allowing a broader audience to use and appreciate the objects. Additionally, collections can be enhanced through the provision of digital representations: gaps in collections can be filled or material that has been geographically dispersed between institutions (such as manuscript material) can be virtually reunited. Early projects believed that digitization of artifacts could also be a form of preservation: this is only the case when the medium of the original is deteriorating, as digital information and media have relatively short life spans themselves; but digitization can also be perceived as a form of preservation when access to the original is restricted and users directed to the digital version of the artifact to reduce the stress of repeated handling on an object. Digitization projects often raise the profile of an institution, showcasing their collections, allowing detailed research to be undertaken, and encouraging outside funding to invest in their infrastructure.^[15]

Many early projects, coming from a long tradition of microfilming, showed initial interests in digitizing text, with the hope the Optical Character Recognition technologies would be able to convert the images into moveable type. In the 1980s, small-scale, in-house projects of limited scope and interest were undertaken, but toward the end of the decade large-scale projects were launched, including pilot projects aiming to investigate the appropriation of digital technologies to the handling of large volumes of information, such as those carried out at the Library of Congress, Cornell University (both the United States), and the Archivo General de Indias (in Spain), sometimes in partnership with commercial computing companies.^[10] The 1990s were termed the “decade of digitization”^[7] as the lowering costs of equipment and storage, and the increased networking possibilities, encouraged most institutions to create digital representations of at least some of their holdings themselves for online display. This was also fostered by many funding opportunities arising around the Millennium, such as that provided by the New Opportunities Fund in the United Kingdom, specifically for the purposes of digitization. Growing user expectations encouraged libraries, museums, and archives to provide images (and related records and metadata) of their material online. Since then, digitization efforts for individual institutions have slowed somewhat, as funding becomes harder to come by, and questions have been raised regarding the costs of digitization and the resulting benefits to institutions. It is all very well to provide images of a medieval manuscript in glorious full color, at great cost, online, but if only three or four scholars in the world are actually interested in looking at it in any great detail, could the money be spent in other ways that are more beneficial to the institution? Questions are now being asked about how we understand value and worth of digitized content.^[16,17] In the early twenty-first century, digital imaging activities have moved beyond digitization of the treasures held in special collections in libraries and archives, back to large-scale commercial partnerships for mass digitization of more general collections to

enable (and experiment with) information searching and retrieval. Industry partners (such as Google or Microsoft) pay for the digitization, getting access to the information in return, and such digitization projects promise to make information available to all via the Internet. However, there is consternation in the publishing industry and the library world regarding issues such as copyright, licensing, and information quality, unanswered questions about technical and managerial procedures, and a fear that such large-scale commercial digitization has a potential to misrepresent, or even damage, the world’s cultural heritage.^[18] We are also only beginning to understand use and usage of large-scale digitized content.^[19] It is now difficult to remember a time when institutions did not provide digital representations of the important materials held in their collection: a recent survey of 1400 European galleries, libraries, archives, and museums showed that 87% of them now have a digital collection,^[20] a rise of 4% since 2012. However, far from everything is available online: on average at time of writing, 17% of collections are digitized across Europe, with further plans to digitize another 52% of institutional holdings across the sector.

Producing digital image versions of holdings through digitization has become an industry in itself, and there is much research devoted to producing guides to best practice in undertaking the digitization of library and archive material. Many early projects were, in effect, experimental case studies, exploring the best way in which to appropriate digital imaging technologies for the Library and information sector. Nowadays, however, guidelines are in place covering all aspects of the digitization process: creating a digital image of an object is just one step in a long chain of procedures that enable digital access to an object, including collections management, object selection, preservation issues, copyright and rights management, technical issues, managing the digital workflow, quality assurance, production of metadata and associated records to allow searching and retrieval, delivering images to users, usability testing, accessibility legislation, and beyond.^[6–8,15]

The need for technical digitization guidelines was highlighted by early projects in the library and archive sector. Given that technologies, standards, and recommendations are constantly changing, the best place to find up-to-date recommendations regarding the technical aspects of digitization is from the online documentation provided by trusted and well-known institutions, such as the frequently updated “Library of Congress Technical Standards for Digital Conversion of Text and Graphic Materials”:^[11] those produced by national bodies such as the U.S. National Archives and Records Association;^[14] those produced by University Libraries, such as the guides available at the California Digital Library (www.cdlib.org/) and the standards advocated by the Digital Library Federation (www.diglib.org/); guides to good practice created and pointed to by the United Kingdom’s Digital

Curation Centre (<http://www.dcc.ac.uk/>); and resources produced by the Jisc Digital Media service (<http://www.jiscdigitalmedia.ac.uk/>), which remains a comprehensive source for all aspects of digitization and digital imaging. Most guides and recommendations are meant to be informative rather than prescriptive, and many cover areas such as management, workflow, delivery, and quality control, as well as providing an insight into up-to-date technical specifications for the production of digital images.

However, although there has been much investment into digital imaging in the Library and Archive sector, there still remain unresolved issues regarding both technical and usability aspects. Benchmarking image quality is difficult as the human visual system varies from operator to operator, and likewise, color management and fidelity is difficult to quantify and manage. Questions still remain about the long-term preservation of digital image files and the resources required to maintain digital image collections in the long term.^[21] The searching and retrieval of digital images is still computationally complex: most systems require adequate metadata regarding the content and provenance of images to be provided, and this can be costly. Evidence of value and levels of use of digitized resources is also scant.^[10,16,17] There are also benefits and opportunities that remain to be explored in using digitized collections further, via “crowdsourcing” of labor to help sort, tag, identify, label, and transcribe images:^[22] how we can best use all this digital image information, now we have it, remains a large issue.

PERSONAL DIGITAL IMAGE COLLECTIONS AND THE LIBRARIAN

Due to the pervasive nature of digital imaging technologies, and the ease with which images can be taken, manipulated, and shared, personal photography has now become vastly more popular than it ever was, and been transformed from a private to a community experience. The online storage and organization of personal digital image collections, often made available to the general public, and made more searchable through the use of tagging, metadata, and online (and mobile phone based) sharing platforms, has been one of the success stories of Web 2.0 (the growing online phenomenon of websites that are community driven, service based, with high-level tools that also harness the collective intelligence of large groups of users). Online services such as Yahoo/Flickr, Google/Picasa, Photobucket, Instagram, Tumblr, Pinterest, and Facebook host hundreds of millions of photographs posted by millions of users. An expanding service industry is growing alongside the user-generated content, providing, for example, online services for ordering digital prints, and facilities for digital photographers to sell or license their images for advertising purposes. Such industries are

undermining traditional photography manufacturers and photo-stock agencies.

Yet users seem to know little about how to archive, preserve, or maintain their personal image data despite photographic industry initiatives such as “Save my Memories.”^[23] Concerns about digital preservation are not only limited to institutional requirements: a child born today may be the most photographed of any generation, but without careful consideration of how these image files are stored, the chances of them being able to see their baby photos in 20 or 30 years are slim. Home computers tend to be seldom backed up or maintained beyond their short lifespan: digital images are emailed and shared online, but seldom printed and stored in archival conditions, meaning loss of the hardware they are stored on means permanent loss of the images themselves. Further research is needed into how digital imaging technology has transformed user habits, and although the industry has started to provide advice for users regarding the long-term preservation and access to their data,^[23] there is increasing concern from the information profession regarding the potential loss of decades of digital images, and any personal digital data, for future use, never mind future generations.^[24–26] To that end, the Library of Congress has recently established a “Personal Archiving” section to give advice to the public about “Preserving your Digital Memories,”^[27] using digital outreach methods to reach as wide an audience as possible to highlight these issues, such as regular guest blog posts in sites that have a large audience.^[28] In the United Kingdom, the Digital Preservation Coalition recently reported on “Personal Digital Archiving,” providing advice for both individuals and information professionals on how to tackle this growing issue.^[29] Other public engagement initiatives undertaken by information professionals, such as the Society of Georgia Archivists’ “Everyday Digital Archives” campaign,^[30] provide a model as to how institutions can inform, educate, and help the general public in both understanding the need for personal archiving of photographic (and other) data, but also how to do so, to ensure their digital photographs are available for future generations. With the rise of social media and image-sharing sites such as Flickr and Instagram, it is also important that people understand issues of privacy and ownership of digital content, and the information community can have an advocacy role in encouraging engagement with the like of the Creative Commons framework^[31] to increase the information literacy^[32] of a wider audience in these increasingly complex areas.

The pervasive nature of digital imaging technologies in the developed world has also led to recent changes in news coverage as the general public can now capture an immediate and personal response to subjects and events that would traditionally be covered by news agencies, often before traditional media outlets are aware of the incident or able to dispatch reporters. This can aid police in their investigations, and calls for the public to submit such

eyewitness material are now commonplace (as is the creation of user-generated video and pictures that counteract official records of events and happening). User generation of digital content is set to become ever more common, and important, blurring the distinction between professional and amateur, democratizing news reporting, and providing historical and judicial evidence. The maintenance and preservation of such digital material for future users, historians, and investigators is the responsibility of the professionals within the media and information environment, and the library and archive sector have role and opportunity in educating the public and media regarding the importance of preserving this information for future generations.

CONCLUSION

Digital imaging technologies, and related advanced in Internet technologies, have changed the way we produce and disseminate visual information, leading to an exponential increase in visual material available in recent years. The Library and Information sector has, through trial and error, developed best practice procedures for the creation of digital image representations of documents and artifacts, and many institutions have undertaken digitization projects to increase access to their holdings. Although successful projects have been undertaken, delivering much image-based content to the user, questions remain regarding the cost, long-term viability, and usefulness of digitized collections. Additionally, the role of the librarian and information professional does not stop at the institution's door: issues regarding the preservation of digital information created by general society, including digital images, are becoming increasingly pressing.

FURTHER READING

A variety of both online and print material exists specifically for the Information professional wishing to know more about digital imaging, and undertaken digitization projects. Print materials such as Besser and Trant,^[5] Kenney and Reiger,^[6] Lee,^[7] Besser,^[9] Terras^[10] are good starting points for those wishing to know more about the technical underpinnings of image files and formats, with a much more detailed account available in Graham^[12] (although this may be a little too technical for those starting out). Online materials, such as Cornell University Library,^[8] Besser,^[9] Library of Congress^[11] and the resources available at the Jisc Digital Media service (<http://www.jiscdigitalmedia.ac.uk/>), also provide good resources regarding all aspects of imaging for the LIS sector. Management issues are dealt with in Lee,^[7] Hughes,^[15] van Horik^[21] raises interesting issues about longevity of digital images and image surrogates and Hughes^[16] covers issues on the impact of digitized content, and what we know of its use. Outreach and public engagement by the sector regarding personal archiving of digital photography collections is covered in Save My Memories,^[23] Library of Congress,^[27] Society of Georgia Archivists,^[30] Public Libraries Online,^[28] Redwine,^[29] and Creative Commons.^[31]

Digital Millennium Copyright Act of 1998

Jonathan A. Franklin

Gallagher Law Library, University of Washington, Seattle, Washington, U.S.A.

Abstract

The Digital Millennium Copyright Act (DMCA) was the most important amendment to U.S. copyright law during the 1990s. Unlike other amendments that altered small but important pieces of the copyright law, the DMCA created an entirely new form of protection that will have wide-ranging effects and has even caused some to suggest it could be the death of copyright. The DMCA was passed by the U.S. Congress and signed by President Clinton in 1998. It amended the U.S. Code, primarily Title 17 of the U.S. Code, part of the federal law that deals with copyright law. The DMCA includes a cluster of discrete copyright-related issues that were combined in one substantial piece of legislation. It covers a wide range of topics, including limiting Internet service provider (ISP) liability, the scope of exclusive rights in ephemeral sound recordings, and protecting boat hull designs. One of the most important sections—the circumvention prohibition—forbids circumvention of technological measures that prevent access to a work.

INTRODUCTION

The Digital Millennium Copyright Act (DMCA) was the most important amendment to U.S. copyright law during the 1990s. Unlike other amendments that altered small but important pieces of the copyright law,^[1] the DMCA created an entirely new form of protection that will have wide-ranging effects and has even caused some to suggest it could be the death of copyright.^[2–4]

The DMCA was passed by the U.S. Congress and signed by President Clinton in 1998.^[5] It amended the U.S. Code, primarily Title 17 of the U.S. Code, part of the federal law that deals with copyright law.^[6] The text of the DMCA and the copyright laws is available online at the Library of Congress Copyright Office.^[7] The DMCA includes a cluster of discrete copyright-related issues that were combined in one substantial piece of legislation. It covers a wide range of topics, including limiting Internet service provider (ISP) liability,^[8] the scope of exclusive rights in ephemeral sound recordings,^[9] and protecting boat hull designs.^[10] One of the most important sections—the circumvention prohibition—forbids circumvention of technological measures that prevent access to a work.^[11] The Act is 58 pages long and divided into five topical sections, or titles. Each title of the DMCA has its own background, history, and implications, and each title is discussed separately below. Two important topics that were in early versions of the bills that became the DMCA, database legislation and parallel import legislation, were excluded from the final version.

TITLE I. WORLD INTELLECTUAL PROPERTY ORGANIZATION TREATIES IMPLEMENTATION

Title I of the DMCA is the enabling legislation for two World Intellectual Property Organization (WIPO) treaties

that were drafted in 1996.^[12] The WIPO is an intergovernmental organization under the United Nations umbrella. It is based in Geneva, Switzerland, and is responsible for the administration of various multilateral intellectual property treaties, including the Berne Convention.^[13] There are over 150 WIPO member states that take part in negotiations on a broad array of intellectual property topics, from protection of folklore to database protection.

There is no such thing as international copyright law. Therefore, once a copyright treaty is finalized, each member state that wants to join that treaty must ratify it and amend its own national laws to conform to the substantive and procedural terms of the treaty. This means that each nation must pass “enabling legislation” to amend its national copyright laws.

Under the U.S. Constitution, the President can negotiate a treaty. However, the President needs the Senate to reject, approve, or conditionally approve a treaty. After two-thirds of the Senate ratifies a treaty, the President deposits it with the originating organization, in this case WIPO. Ideally, the implementing legislation, which goes through both the House and the Senate, should be completed prior to depositing the treaty.

For the same treaty, one jurisdiction might have only minor amendments, while another jurisdiction joining the same treaty might have to rewrite large portions of its copyright laws to conform to the new instrument. It is important to remember that these treaties serve to establish minimum standards, and, as discussed below, countries may amend their national laws to protect copyrights well beyond the terms of the treaty.

The two treaties enabled by the DMCA are the WIPO Copyright Treaty (WCT)^[14] and the WIPO Performances and Phonographs Treaty (WPPT).^[15] The WCT implemented several relatively noncontroversial legal

requirements, including recognizing that authors have the right to control the distribution of their works (with first sale exceptions being determined on a national basis), providing for exclusive rental rights for certain types of works, and increasing the term of protection for photographic works to 50 years.^[16] The WPPT covered the rights of performers and music producers in their creations. These issues had already been largely addressed in U.S. copyright law.

Title I of the DMCA amends the copyright law to include a section prohibiting circumvention of access controls.^[17] Access controls are technological locks that prevent users from copying the underlying digital information. For example, CDs do not have any access controls, and hence can easily be copied. DVDs, on the other hand, have access controls that prevent the user from skipping certain portions of the introductory content and copying the disc. This section of the DMCA also includes a section that prevents tampering with copyright management information, such as digital identifiers of the title of the work, the author of the work, and relevant licensing terms.^[18] It also includes civil and criminal penalties for violations of the copyright management information tampering provisions and the anticircumvention provisions. The maximum penalty on the criminal conspiracy charge is 5 years of imprisonment and a \$500,000 fine;^[19] the maximum penalty for each of the civil charges is 5 years of imprisonment and a \$250,000 fine.^[20]

Anticircumvention

The most important section of the WCT, from the perspective of U.S. copyright law, is Article 11, the rationale for the important anticircumvention provisions of the DMCA.

Article 11 states:

Contracting Parties shall provide adequate legal protection and effective legal remedies against the circumvention of effective technological measures that are used by authors in connection with the exercise of their rights under this Treaty or the Berne Convention and that restrict acts, in respect of their works, which are not authorized by the authors concerned or permitted by law.^[14]

Article 18 of the WPPT includes virtually the same language.^[15] Although some have suggested that existing U.S. law was sufficient to meet the requirements of Article 11,^[21] industries concerned with the distribution of their digital content lobbied for a new form of protection in U.S. law.^[22] This protection is based not on copyright (i.e., the right to copy), but on the right of access (i.e., the right to read, view, or experience the work in the first place).^[23,24]

Access rights

Section 1201(1)(a) of the copyright law as added by the DMCA states: “No person shall circumvent a

technological measure that effectively controls access to a work protected under this title.”^[25] A technological measure “[e]ffectively controls access to a work . . . if the measure, in the ordinary course of its operation, requires the application of information, or a process or a treatment, with the authority of the copyright owner, to gain access to the work.”^[26] In other words, if the copyright owner or representative has supplied a mathematical formula or code to make a video readable by the video-playing machine, the work is effectively controlled. There is the potential for substantial litigation about the word “effectively,” because some types of encryption, whether pig Latin or a simple mathematical transposition, are arguably ineffective, even though they are required in the ordinary course of operation. If, and only if, access to the work is “effectively controlled” does the second phrase, “circumvent a technical measure,” become relevant. “Circumvent a technological measure . . . means to descramble a scrambled work, to decrypt an encrypted work, or otherwise avoid, bypass, remove, deactivate, or impair a technological measure, without authority of the copyright owner.”^[27] Thus, if a user circumvents an effective access control, regardless of intent, there has been a violation of this section. Notice that this section requires that the work be “protected under this title.” It is possible that this clause will be used by courts in the future to limit the scope of the DMCA to only those works that are currently protected by copyright.

There are a few narrow exceptions to the anticircumvention provisions, notably for law enforcement, reverse engineering, and encryption research.^[28] For example, reverse engineering of software is permitted if certain conditions are met and if the sole purpose of the circumvention is to achieve interoperability.^[29] The exception for nonprofit libraries, archives, and educational institutions permits access “to make a good faith determination of whether to acquire a copy of the work.”^[30] There is also a triennial rule-making mechanism, discussed below, that can result in additional exceptions.

It is important that the technological measure control “access,” not “copying.” Even though the DMCA amends the copyright law, the anticircumvention provisions of the DMCA, sometimes called paracopyright,^[31] are fundamentally different from the rest of the copyright law. Copyright is a constitutionally mandated legal balance between the interests of creators of protected works and society. The U.S. Constitution states: “Congress shall have the power . . . [t]o promote the progress of science and useful arts, by securing for limited times to authors and inventors the exclusive right to their respective writings and discoveries.”^[32] This is achieved by granting creators specific exclusive rights to control certain aspects of their work for a limited time, after which the work becomes part of the public domain, and the exclusive rights cease to exist. In contrast to the balance between the incentive to create and the benefit to society found in copyright law,

the anticircumvention provisions have no such balance. If a technological measure effectively controls access to a work, there is no time period after which there is a right to decrypt it or any fair use right that trumps the anticircumvention provisions.^[33]

Access controls prevent the user from using the work, including viewing it. Copy controls prevent the user, who can view the work, from copying it. The important distinction is that the DMCA permits circumvention of a measure that prevents copying, but not circumvention of a measure that prevents access. It states “[n]othing in this section shall affect rights, remedies, limitations, or defenses to copyright infringement, including fair use, under this title.”^[34] If you can legitimately gain access, then you can still exercise your fair use rights and other rights embodied in traditional copyright law. However, because you cannot copy what you cannot access, and content providers know access controls cannot be circumvented, there is great incentive for content providers to use technological measures to limit access, thereby preventing potential copiers from ever reaching the work. To restore the balance of copyright law to the access rights, scholars opposed to the DMCA have proposed expanding fair use to include access rights or creating a new right of access.^[24] For other articles discussing the relationship between the DMCA and public interest concerns, see Cohen^[35] and Samuelson.^[36] For a different perspective, see Ginsburg.^[37]

Device trafficking

Along with the prohibition of circumvention in most cases, one cannot “manufacture, import, offer to the public, provide, or otherwise traffic” in devices or methods if they are primarily designed or produced to circumvent; they have only limited commercially significant purpose or use other than to circumvent; or they are marketed for use in circumventing.^[38] Additionally, users cannot avoid, bypass, remove, deactivate, or otherwise impair a technological measure that effectively protects a right of a copyright owner under Title 17. Finally, they cannot traffic in devices that bypass technological measures.^[39] Together, these device trafficking prohibitions are much like prohibiting the sale of lock-picking tools if those tools have no other purpose. However, most prohibitions against lock-picking tools require the owner to have some level of intent to use them in an illegal way. To the extent that fair use is extended to access rights, there will need to be legal mechanisms that permit the distribution of devices to facilitate legitimate circumvention. Otherwise, only the technological elite will be able to avail themselves of these access rights. Both device trafficking sections require that the works be “protected under this title,” suggesting that perhaps devices that are designed in large part to circumvent access controls blocking access to public domain works or uses are permissible.

“Particular Class” Rule Making

The DMCA also requires the Librarian of Congress to conduct rule making 2 years after enactment, and every 3 years thereafter, to define “particular classes” to exclude from the anticircumvention provisions.^[40] The rules can only permit circumvention of access to a defined class of works by all users, rather than permit access by the type of use or user. This means that the rule making would have to justify permitting access to the least favorable user, e.g., a direct competitor or consumer in the marketplace, rather than permitting access exclusively to researchers or for educational purposes. The narrow constraints of the rule-making framework minimize the potential for them to ameliorate the more socially detrimental aspects of the DMCA. The first rule making defined only two exempted classes, lists of blocked Web sites and literary works rendered unusable due to inoperative control devices.^[41] More recent rule making has created exceptions that permit circumvention in other cases, such as circumventing DVD copy protection systems to create clip reels, circumventing digital locks in cell phones that prevent the user from changing carriers, and circumventing the access controls on e-books if there is no version that permits them to be read aloud.^[42]

The scope of the rule making is limited by the DMCA to address anticircumvention, not device trafficking. By excluding devices from the scope of the review, even if an access right is recommended, each individual exercising that right would need to achieve the technological sophistication to circumvent the controls without the assistance of a distributed device, an extremely unlikely scenario.

Section 104 Report

The anticircumvention and antitrafficking sections of the DMCA did not become effective until 2 years after passage of the Act. The DMCA also required the drafting of a report that addressed the relationship between the DMCA and parts of the copyright law, notably section 109,^[43] the first sale doctrine, and section 117,^[44] the section that permits the making of archival copies of computer programs. The Librarian of Congress, based on the recommendations of the Register of Copyrights and the Assistant Secretary of Commerce, issued the report in 2001.^[45]

The report addresses three proposals: creation of a “digital first sale doctrine,” creation of an exemption for the making of certain temporary incidental copies, and the expansion of the archival copying exemption for computer programs in section 117 of the Act.^[45] The comments related to the first sale doctrine discuss whether the societal benefits of the first sale doctrine should be carried over into the digital realm, where the “loan” of a digital work is really the making of a copy and the concurrent deletion of

the original.^[45] The concern of opponents is that this would lead to widespread piracy and destruction of the market for the legitimate original if the originals are not deleted.^[45] This is a particular concern for digital works, because, unlike analog works, there is no degradation of quality when a copy is copied.

There is substantial scholarship on trusted systems,^[46–49] systems that automatically delete the original when sending the copy. In light of the infancy of such systems, the report concluded, “Given the relative infancy of digital rights management, it is premature to consider any legislative change at this time. Should this practice become widespread, it could have serious consequences for the operation of the first sale doctrine, although the ultimate effect on consumers is unclear.”^[50] An additional concern was the effect of anticircumvention legislation on the creation of archival copies of software.^[50] The report addressed that point as well, stating:

The library community has raised concerns about how the current marketing of works in digital form affects libraries with regard to five specifically enumerated categories: interlibrary loans, off-site accessibility, archiving/preservation, availability of works, and use of donated copies. Most of these issues arise from terms and conditions of use, and costs of license agreements. One arises because, when the library has only online access to the work, it lacks a physical copy of the copyrighted work that can be transferred.

These issues arise from existing business models and are therefore subject to market forces. We are in the early stages of electronic commerce. We hope and expect that the marketplace will respond to the various concerns of customers in the library community. However, these issues may require further consideration at some point in the future. Libraries serve a vital function in society, and we will continue to work with the library and publishing communities on ways to ensure the continuation of library functions that are critical to our national interest.^[50]

Cases

Several cases have dealt with the issues raised by anticircumvention provisions of the DMCA. One recent District Court opinion rejected the argument that there was a fair use right to access.^[35] The most important cases attempt to invalidate the anticircumvention sections on Constitutional grounds and are discussed in the following sections.

Two important types of challenges to the anticircumvention provisions of the DMCA are likely. The first challenge will be claims that by preventing circumvention of access controls when the underlying works are partially or completely in the public domain, the DMCA oversteps the authority granted by Congress in

the Patent and Copyright Clause of the U.S. Constitution. The intent of the Patent and Copyright Clause is to create an incentive for creators to create; thereby subsequently benefiting all of society after the limited term of the exclusive rights comes to an end. Since the term of protection for public domain works has expired, Congress may lack the authority to protect them further.^[34,51,52] Because Congress is only granted the power to secure exclusive rights for a limited time, the anticircumvention provisions arguably exceed the scope of the powers of Congress by permitting the encryption of public domain material without a right of circumvention. It is possible that the DMCA could survive this Constitutional challenge, either because a court determines it does not exceed the scope of that clause or because the DMCA is considered within the scope of Congressional power under another Constitutional clause, such as the Commerce Clause.^[53]

The second challenge will be that the DMCA is unconstitutional, because it is in conflict with the First Amendment. The success of Constitutional challenges to the DMCA will largely hinge on the level of scrutiny the court applies. Even if a court decides that the prevention of copyright piracy is an “important or substantial governmental interest,”^[54,55] the DMCA could be declared unconstitutional, because the DMCA cannot “burden substantially more speech than necessary.”^[55] The court would then have to determine if less restrictive means could reach the same end, such as preventing copying, but not blocking access. Whether the court would consider the technological feasibility of the alternatives as of the time of passage of the DMCA or as of the time of lawsuit raises interesting issues and, if the latter, suggests that subsequent attacks on the DMCA might be successful, even if earlier ones failed. What follows is a discussion of several recent cases that touch on the relationship between the First Amendment and the DMCA.

DeCSS case (*MPAA v. Corley*)

DVD discs include a content scrambling system (CSS).^[56] DVD players include chips that permit them to play DVDs that use the CSS. Without “decoding” the DVDs, the content on them is not viewable. A program was written, called DeCSS, which makes DVDs playable on devices other than licensed DVD players, including computers running the Linux operating system. To achieve this goal, the program decrypts the CSS on the DVD and uses the information to make the content on the DVD viewable on unlicensed players that lack the special chip.^[57] Although DVDs can be copied without breaking the CSS, so long as the CSS is not circumvented, the content cannot be viewed, except on licensed players. The CSS is a type of access control.

The DeCSS case arose when an online magazine posted the DeCSS program and hyperlinked to other sites that posted the DeCSS program.^[58] There are two issues in

the DeCSS case: whether, under the DMCA, Web sites can be liable for posting the code to decrypt the DVDs; and whether Web sites can be liable for knowingly linking to sites that post the code to decrypt the DVDs. The Web sites raised constitutional First Amendment concerns, because a limitation on posting programs or linking to programs limits the ability of the Web site owner to communicate, and hence free speech.

To address these questions, the court determined that CSS was “effective” and that decrypting CSS to play DVDs on unlicensed players, such as computers running Linux, was not within the interoperability exception.^[58] In addressing the free speech issue, the court applied the O’Brien test, because the DMCA targeted functional speech, rather than expressive speech, and the speech limitation was considered content neutral, meaning that it did not attempt to discriminate against certain types of content.^[58] The court upheld the constitutionality of the DMCA in both the posting and linking scenarios. It found that in the context of the DMCA, there was an “important or substantial governmental interest” and that the DMCA avoided burdening substantially more speech that is necessary to further the government’s legitimate interests.^[58] In the context of linking, it upheld the District Court’s linking test that found that limiting some acceptable speech was Constitutionally acceptable, even though the alternative of limiting less speech and tolerating some decryption would have reduced the burden on speech, but at the cost of the potential for widespread piracy.^[58]

Felten case (*Felten v. RIAA*)

Professor Edward Felten of the Computer Science Department at Princeton University researched music samples distributed by the Secure Digital Music Initiative (SDMI).^[59] These samples included watermarks that could be detected by players or recorders to prevent duplication. The challenge was to remove the watermarks without overly degrading the sound quality.^[60] After Professor Felten’s group achieved this goal, they wanted to present their results. In a complicated set of facts, SDMI and others suggested that presenting their results might violate the licensing agreement Professor Felten had agreed to prior to receiving the samples or might violate the DMCA, because their research could help others defeat the watermarking system, which was already in public use outside the challenge.^[60] Professor Felten sued to be able to present his results. After initially not presenting their results, his research team did so at a subsequent conference, with the permission of SDMI and others. After presenting his results at a conference, but arguing that there was still a controversy because future research would be chilled, a court determined that the issue was moot, because there was no continuing controversy.^[61] Along with threat of DMCA and breach of contract claims, the Felten litigation team raised First Amendment

free speech claims, suggesting that the DMCA was being used to censor discussions about encryption research.^[62]

The Felten case highlights two important effects of the DMCA: the potential chilling effect of such broad legislation and the role of contracts in potentially preventing access to both copyright-protected and public domain content. Professor Felten received e-mail that suggested he might face liability if he presented his paper. Even though he subsequently presented it, the threat of liability might stifle research in the encryption and computer security areas. The concern is that this would be detrimental to the U.S. economy, because there would then be reliance on systems that are not secure. The counter to this argument is that the process of encrypting content and unauthorized decryption will lead to a great deal of wasted effort spent trying to encrypt and decrypt content and that it is better that those efforts be spent in other areas. This argument is put forth along with the suggestion that the exemptions within the DMCA are sufficient for research in these areas.^[63]

The Felten case is also different from the DeCSS case in that Professor Felten agreed to contractual terms prior to receiving the SDMI samples. Contracts, particularly nonnegotiable shrinkwrap or clickwrap licenses, are the legal equivalents of the technological access controls in the DMCA. If a nonnegotiable clickwrap agreement is a contract, then the agreeing party will be bound by the terms of the contract. Although there are certain exceptions, the drafters of these licenses to circumvent the balance in copyright law by eliminating the acquirer’s first sale and fair use rights, just the way access controls can technologically prevent exercise of first sale and fair use rights.

The 104 Report addressed this point:

On the other hand, the movement at the state level toward resolving questions as to the enforceability of non-negotiated contracts coupled with legally-protected technological measures that give right holders the technological capability of imposing contractual provisions unilaterally increases the possibility that right holders, rather than Congress, will determine the landscape of consumer privileges in the future. Although market forces may well prevent right holders from unreasonably limiting consumer privileges, it is possible that at some point in the future a case could be made for statutory change.^[64]

The Court dismissed the case as moot after the RIAA promised not to sue Professor Felten for publicly presenting his research.^[65]

Sklyarov case (*U.S. v. ElcomSoft*)

The third important DMCA case is the case of the Russian programmer, Dmitry Sklyarov, who was arrested in the United States while attending a conference on

e-books.^[66,67] The Sklyarov case was notable, because it was a criminal prosecution, unlike the other two cases, which were civil cases for monetary damages. Dmitry Sklyarov works for ElcomSoft, a Russian company that creates and sells software that circumvents access controls on e-books. This is a legal product in Russia but not in the United States, due to the DMCA. After a substantial period of detention in the United States, Sklyarov was released in late 2001 on the condition that he testifies against his employer, ElcomSoft.^[68] A U.S. jury subsequently cleared ElcomSoft on all charges.^[69]

Arguably, the Sklyarov scenario is precisely the reason the DMCA was passed, but it also highlights the complexity of enforcing laws in an area where the laws and norms vary widely from country to country. In fact, the European equivalent of the DMCA has numerous provisions that differ substantially from the DMCA.^[70] Given that circumvention of access controls and distribution of software devices that circumvent access controls are facilitated by Internet access, issues of jurisdiction and enforcement of judgments are likely to become more important in the coming decades.

Lexmark case (*Lexmark Int'l v. Static Control Components, Inc.*)

Lexmark sold laser printers and toner cartridges. The toner cartridges had a chip in them that enabled them to work with their printers. Competitors could not sell replacement toner cartridges because without the chip, the printer would not operate. The defendant manufactured chips that would enable non-Lexmark toner cartridges to work with Lexmark printers. Lexmark sued, claiming a DMCA violation and won at the District Court.^[71] The Court of Appeals subsequently reversed the District Court's opinion.^[72] The case is notable because it prevented the scope of the DMCA from expanding into a realm where interoperability and competition would be hampered by permitting manufacturers to use the DMCA to block competition in areas approaching patent law. For a related case regarding garage door openers, see *Chamberlain v. Skylink*.^[73]

DVDCopy case (*321 Studios v. Metro-Goldwyn-Mayer Studios, Inc.*)

DVDCopy, produced by 321 Studios, was software that permitted users to copy their DVDs. 321 Studios was sued because the software circumvented the access controls on the DVD. Even though the end users could do what the software permitted them to do, the District Court held that 321 Studios was still liable for selling the tool that permitted the end user to decrypt the DVD.^[74] This case highlights that even if tech-savvy end users can legally do certain things, those who lack the savvy will not be able to take advantage of the rights that they do have. In

addition, 321 Studios made certain constitutional arguments that the court largely rejected.

Bnetd case (*Davidson & Associates v. Jung*)

Blizzard created Battle.net as a server-based application that would permit players of Blizzard games to find each other online players and play online.^[75] Among other things, it checked to see if the user's copy of the software was legal. Bnetd.org was designed to serve the same purpose as Battle.net, but lacked some features, such as the authentication of the user's copy of the software. When Blizzard sued bnetd, part of bnetd's defense relied on analogizing to the Lexmark Case. The court rejected that analogy, suggesting that the difference between the two is that the acquisition of the printer provides access to the relevant programs, while in the bnetd case, no one ever gets access to the Battle.net code, so the DMCA does apply. In addition, the court stated that the interoperability exception did not apply, suggesting that the lack of a check that the user's software was legal made a substantial difference.

TITLE II. ONLINE COPYRIGHT INFRINGEMENT LIABILITY LIMITATION

Title II of the DMCA addresses the twin concerns of content providers and ISPs.^[76] Prior to the DMCA, content providers were concerned that, without the threat of liability, ISPs would facilitate the distribution of pirated digital content. ISPs were concerned that they would be liable for money damages for infringing copyrights by distributing or hosting protected content. Because copyright law grants creators exclusive display and performance rights, ISPs might be directly, contributorily, or vicariously infringing the owner's rights. The ISPs were particularly concerned, because the person who actually posted the content would probably not be as well off as the ISP, would be harder to trace, and might be a more sympathetic defendant, leaving the ISP to become the primary defendant in online copyright suits.

A compromise was struck wherein Title 17 of the U.S. Code, the copyright law, was amended by adding a new section 512. It set forth that ISPs would not be liable for hosting or transmitting content so long as they had registered contact information, had no actual knowledge of copyright infringements, and cooperated with processes to disable access and limit the harm to the copyright owner following a valid notification of a violation.^[77] Section 512 is extraordinarily detailed. It lays out an elaborate roadmap for ISPs wishing to avoid liability for caching, storage, and transmission of protected works.

In the Napster case, dealing with whether the decentralized file sharing service that did not host any information itself could be found liable for secondary

copyright infringement, one of the issues in the Napster case was whether Napster could invoke this liability limitation.^[78] Napster was a service in which a server indexed music files on users' computers and facilitated users copying files from other users' personal computers. Napster was not an intermediary in the copying of files. Although the Napster model could be used to distribute public domain content, most of the content distributed via Napster was protected content.^[78] On appeal, the court suggested that this section of the DMCA was intended to provide relief to vicarious infringers in some contexts but did not opine on whether such an analysis would include Napster.^[78] Other cases have confirmed that companies like Amazon^[79] and eBay^[80] are able to take advantage of this limitation. The issue of whether search engines, such as Google, are able to take advantage of section 512 is currently being litigated.^[81]

More recently, the major case law has involved service provider liability for repeat infringement by users.^[82]

TITLE III. COMPUTER MAINTENANCE AND REPAIR COPYRIGHT EXEMPTION

This section, also known by its short title, the "Computer Maintenance Competition Assurance Act" amends section 117 of the copyright law to overrule a case that held that if software was licensed and a service company came to maintain the computer, by turning the computer on, the party servicing the computer was creating an illegal copy of the program in the memory of the computer.^[83] This section permits the making of a copy in the memory of the computer if the purpose of the use is to repair or maintain the hardware.^[84] This section does not apply to software to the extent that the exemption does not apply if the copy is made when the software is "not necessary for that machine to be activated."^[85]

TITLE IV. MISCELLANEOUS PROVISIONS

Title IV amends various parts of the copyright law to address issues related to distance education, libraries, and ephemeral recordings, among other things. Due to the concerns of educators, the DMCA required the Register of Copyrights to issue a report on how to promote distance education through digital technologies.^[86] After an intense 6 mo review, the report suggested nine changes:

1. Clarify the meaning of transmission to include both digital and analog.
2. Expand coverage of rights to the extent technologically necessary.
3. Emphasize the concept of mediated instruction. Ensure that the performance or display is analogous to the type of performance or display that would take

place in a live classroom setting, rather than a substitute for the original.

4. Eliminate the requirement of a physical classroom, but substitute the requirement of official enrollment to limit abuses of distance education.
5. Add new safeguards to counteract new risks, such as using technological measures to control unauthorized use and educating students and faculty on copyright law.
6. Maintain existing standards of eligibility.
7. Expand categories of works covered.
8. Require use of lawful copies.
9. Add new ephemeral recording exemption.^[86]

Section 404 of the DMCA updates the library exemption, section 108 of the copyright law,^[87] to meet current archival needs and standards. This section permits archives to make three copies of archival works, one as the master, one as the archival copy, and one as the use copy. Additionally, the copy no longer has to be a facsimile, but it can reform the content. Libraries cannot distribute digital content in the same way that they are permitted to distribute the analog facsimiles. Although print works could become damaged or stolen, existing section 108 did not address the library's needs when the digital format was unreadable. This section of the DMCA added that archival copies could be made when the format became obsolete. Obsolete is defined as "if the machine or device necessary to render perceptible a work stored in that format is no longer manufactured, or is no longer reasonably available in the commercial marketplace."^[88] Finally, if no notice of copyright appears on the work, the library can state that the work "may be protected by copyright."^[89]

Sections 402 and 405 of the DMCA address the issue of ephemeral recordings and reconcile previous copyright legislation and the anticircumvention provisions with the need for broadcast organizations to make ephemeral copies of their programming. Another section defined the scope of exclusive rights in sound recordings as they pertain to ephemeral recordings.^[90]

TITLE V. PROTECTION OF CERTAIN ORIGINAL DESIGNS

Title V, also known by its short title, "Vessel Hull Design Protection Act," protects boat hull designs for 10 yr.^[91] There is a long and contentious history of protection of boat hull designs.^[92] Boat hull designs, like digitized music, can be very hard to create and very easy to copy. In the context of boat hulls, they are copied through the use of plug molds. To qualify for protection, the design has to be registered, and notice of protection would be required.^[93] The section includes exceptions for educational uses, independent creation, and liability for resellers if there was no notice of protection.^[94]

Digital Object Identifier (DOI®) System

Norman Paskin

Tertius Ltd., Oxford, U.K.

Abstract

The Digital Object Identifier (DOI®) System is a managed system for persistent identification of content on digital networks. It can be used to identify physical, digital, or abstract entities. The identifiers (DOI names) resolve to data specified by the registrant, and use an extensible metadata model to associate descriptive and other elements of data with the DOI name. The DOI system is implemented through a federation of registration agencies, under policies and common infrastructure provided by the International DOI Foundation which developed and controls the system. The DOI system has been developed and implemented in a range of publishing applications since 2000; by early 2009 over 40 million DOIs had been assigned. The DOI system provides identifiers which are persistent, unique, resolvable, and interoperable and so useful for management of content on digital networks in automated and controlled ways.

IDENTIFIER CONCEPTS

An identifier is a concise means of referencing something. The term “identifier” can mean several different things:

- A “string,” typically a number or name, denoting a specific entity (the referent of the identifier string). For example, the identifier ISBN 978-0-00-721331-3 denotes the book “Francis Crick” by Matt Ridley.
- A “specification,” which prescribes how such strings are constructed. For example, the ISO standard ISO 2108:2005^[1] is the current specification of the ISBN numbering system; but having that standard alone will not enable someone to construct and register a new valid ISBN.
- A “scheme,” which implements such a specification. For example, the ISBN International Agency^[2] implements the ISBN standard in an implemented scheme, by assigning ISBN prefixes to publishers, registering specific ISBNs (strings); providing rules on use of the ISBN (such as the incorporation of the ISBN as a bar code on the cover of a book). Typically, such schemes provide a managed registry of the identifiers within their control, in order to offer a related service.

Some important concepts relating to identifiers are “uniqueness,” “resolution,” “interoperability,” and “persistence.”

Uniqueness is the requirement that one string denotes one and only one entity (the “referent”). Note that the converse is not a logical consequence: it is not necessary that an entity have only one identifier. For example, a book may have an ISBN and also an LCCN. An identifier scheme may even allow multiple identifiers for one entity, though usually these are deprecated.

Resolution is the process in which an identifier is the input to a service to receive in return a specific output of

one or more pieces of current information related to the identified entity. For example, a bar code ISBN in a bookshop is scanned by a bar code reader and resolves to some point of sale information, such as title and price. Note that resolution depends on a particular application: while a bar code in a bookshop may resolve to price, the same bar code in a warehouse application might resolve to current stock number, or pallet position. Another familiar example of resolution is the Internet Domain Name System (DNS) which resolves a domain name address (URL) to a file residing on a specific host server machine.

Interoperability denotes the ability to use an identifier in services outside the direct control of the issuing assigner: identifiers assigned in one context may be encountered in another place or time without consulting the assigner. This requires that the assumptions made on assignment will be made known in some way. For example, a customer may order a book from a bookseller or a library system by quoting its ISBN, without consulting the publisher who assigned the number.

Persistence is the requirement that once assigned, an identifier denotes the same referent indefinitely. For example, ISBNs, once assigned, are managed so as to reference the same book always (and are not reassigned). Persistence can be considered to be “interoperability with the future.”

The management of content on digital networks requires identifiers to be persistent, unique, resolvable, and interoperable. As an example, URLs do not identify content but a file location: using them as a substitute for such identifiers is not sustainable for reliable automation. The content may be removed (“404 not found”), or changed (not being the same as the user anticipated, or the user being unaware of such change). There have been a number of efforts to address the need for such reliable identifiers, notable among them URN^[3] and

URI^[4] specifications; however these do not of themselves provide an implemented managed scheme and registry for specific content sector applications. Such full schemes require more: a model for identifiers and their management; shared, standards-based, persistent identifier management infrastructure; support for adoption of persistent identifiers and services, and a plan for sustainable shared identifier infrastructure.^[5,6] The Digital Object Identifier (DOI®) system is such a managed system for persistent identification of content on digital networks, using a federation of registries following a common specification.

The uncapitalized term “digital object identifier” may be used nonspecifically to describe a number of varied technologies concerned with the identification of entities in a digital environment. The capitalized term “Digital Object Identifier” refers to one specific system defined and managed by the International DOI Foundation,^[7] which provides an infrastructure for persistent unique identification of entities (here termed “objects”) on digital networks deployed in a number of content-related applications.

DOI SYSTEM: OUTLINE

DOI is an acronym for Digital Object Identifier. The DOI system provides for unique identification, persistence, resolution, metadata, and semantic interoperability of content entities (“objects”). Information about an object can change over time, including where to find it, but its DOI name will not change.

The DOI system brings together

- A syntax specification, defining the construction of a string (a DOI name)
- A resolution component, providing the mechanism to resolve the DOI name to data specified by the registrant
- A metadata component, defining an extensible model for associating descriptive and other elements of data with the DOI name
- A social infrastructure, defining the full implementation through policies and shared technical infrastructure in a federation of registration agencies

More detail on each of these aspects is given later in this entry.

The DOI system operates through a tiered structure:

- The International DOI Foundation is the umbrella organization defining the rules and operation of the system. It is a non-profit member-funded organization.
- Registration agencies are all members of the International DOI Foundation, and have a contractual

arrangement with the Foundation including a license to operate the DOI system. They provide defined services in specific sectors or applications. DOI registration is normally only a part of the service such an organization offers, since assignment of an identifier is usually done for the purpose of a specific initial service or application. An example is the CrossRef registration agency,^[8] which provides services to publishers for linking reference citations in articles based on DOI-identified articles. Registration agencies may collaborate, or remain relatively autonomous.

- DOI names are registered by clients via a registration agency (e.g., in the case of the CrossRef agency, individual publishers are clients using the CrossRef service). Part of this process may be undertaken by the registration agency, as part of its service offering. If a suitable registration agency cannot be found for a certain sector, the International DOI Foundation will seek to appoint one.

DOI is a registered trademark of the International DOI Foundation, Inc. (abbreviated to IDF). The preferred usage, to avoid ambiguity, is with a qualifier to refer to either specific components of the DOI system (e.g., “DOI name”: the string that specifies a unique referent within the DOI system); or the system as a whole (“DOI system”: the functional deployment of DOI names as the application of identifiers in computer-sensible form through assignment, resolution, referent description, administration, etc.).

SCOPE

The term “Digital Object Identifier” is construed as “digital identifier of an object,” rather than “identifier of a digital object”: the objects identified by DOI names may be of any form—digital, physical, or abstract—as all these forms may be necessary parts of a content management system. The DOI system is an abstract framework which does not specify a particular context of its application, but is designed with the aim of working over the Internet.^[9]

A DOI name is permanently assigned to an object, to provide a persistent link to current information about that object, including where it, or information about it, can be found. The principal focus of assignment is to content-related entities; that term is not precisely defined but is exemplified by text documents; data sets; sound carriers; books; photographs; serials; audio, video, and audiovisual recordings; software; abstract works; artwork, etc., and related entities in their management, for example, licenses or parties. A DOI name is not intended as a replacement for other identifier schemes, such as those of ISO TC46/SC9^[10] ISBN, ISSN, ISAN, ISRC, etc., or other

commonly recognized identifiers: if an object is already identified with another identifier string, the character string of the other identifier may be integrated into the DOI name syntax, and/or carried in DOI metadata, for use in DOI applications.

A DOI name may be assigned to any object whenever there is a functional need to distinguish it as a separate entity. Registration agencies may specify more constrained rules for the assignment of DOI names to objects for DOI-related services (e.g., a given registration agency may restrict its activities to one type of content or one type of service).

SYNTAX

A DOI name is the string that specifies a unique object (the referent) within the DOI system. The DOI syntax (standardized as ANSI/NISO Z39.84-2005)^[11] prescribes the form and sequence of characters comprising any DOI name. The DOI syntax is made up of a “prefix” element and a “suffix” element separated by a forward slash. There is no defined limit on the length of the DOI name, or of its prefix or its suffix elements. The DOI name is case-insensitive and may incorporate any printable characters from the Unicode Standard.

- Example: a DOI name with the prefix element “10.1000” and the suffix element “123456”: 10.1000/123456

The combination of a unique prefix element (assigned to a particular DOI registrant) and a unique suffix element (provided by that registrant) is unique, and so allows the decentralized allocation of DOI numbers. The DOI name is an opaque string for the purposes of the DOI system: no definitive information should be inferred from the specific character string of a DOI name. In particular, the inclusion in a DOI name of any registrant code allocated to a specific organization does not provide evidence of the ownership of rights or current management responsibility of any intellectual property in the referent. Such information can be asserted in the associated DOI metadata.

The DOI prefix has two components: a “Directory” indicator followed by a “Registrant” code, separated by a full stop (period) (e.g., 10.1000). The directory indicator is always “10” and distinguishes the entire set of character strings (prefix and suffix) as DOIs within the wider Handle System[®] used for resolution. The registrant code is a unique alphanumeric string assigned to an organization that wishes to register DOI names (four digit numeric codes are currently used though this is not a compulsory syntax). The registrant code is assigned through a DOI registration agency, and a registrant may have multiple-registrant codes. Once a DOI name is assigned the string should not be changed, regardless of any changes in the ownership or

management of the referent object; if an object is withdrawn from digital access, its DOI name should still resolve to some appropriate message to this effect.

The DOI suffix may be a sequential number, or it may incorporate an identifier generated from or based on another system used by the registrant (e.g., ISBN, ISSN, ISTC). In such cases, the existing system may specify its own preferred construction for such a suffix:

- Example: a DOI suffix using an ISSN: 10.1038/issn.0028-0836.

When displayed on screen or in print, a DOI name is normally preceded by a lowercase “doi”: unless the context clearly indicates that a DOI name is implied.

- Example: the DOI name 10.1006/jmbi.1998.2354 is displayed as doi:10.1006/jmbi.1998.2354.

The use of lowercase string “doi” follows the specification for representation as a URI (as for e.g., “ftp:” and “http:”).

DOI names may be represented in other forms in certain contexts. For example, when displayed in Web browsers the DOI name itself may be attached to the address for an appropriate proxy server (e.g., <http://dx.doi.org/> resolves DOIs in the context of Web browsers using the Handle System resolution technology) to enable resolution of the DOI name via a standard Web hyperlink.

- Example: the DOI name 10.1006/jmbi.1998.2354 would be made an active link as <http://dx.doi.org/10.1006/jmbi.1998.2354>.

DOI names so represented in a URL and transported by the HTTP protocol are constrained to follow standard IETF guidelines for URI representations. The syntax for URIs is more restrictive than the syntax for DOIs; some characters are reserved and will need encoding (the NISO Z39.84 DOI syntax standard provides more detail). Certain client or server software may be able to handle DOIs using native handle resolution technology (where doi:10.1006/jmbi.1998.2354 would be understood by the browser and automatically resolved without the addition of the proxy server address). DOI names may also be represented in other schemes, for example, in the info URI schema^[12,13] as info:doi/10.1006/jmbi.1998.2354.

RESOLUTION

A DOI name can, within the DOI system, be resolved to values of one or more types of data relating to the object identified by that DOI name, such as a URL, an e-mail address, other identifiers, and descriptive metadata (or any additional types defined extensibly by the registration agency). Resolution is the process of submitting a specific

DOI name to the DOI system (e.g., by clicking on a DOI in a Web browser) and receiving in return the associated values held in the DOI resolution record for one or more of those types of data relating to the object identified by that DOI name. Since the referent objects referred to by DOI names may be of various types (including abstractions as “works,” physical “manifestations,” performances), they may or may not be directly accessible in the form of a digital file or other manifestation; hence the resolution may or may not return an instance of the object.

The initial implementation of DOI system was that of persistent naming: a single redirection from a DOI name to a digital location (URL) of the entity (Fig. 1).

A significant DOI function is the capability for multiple resolution, that is, delivering more than one value back from a resolution request. The values are grouped into defined types, which can form the basis of services (Fig. 2). An example of current usage of this facility is resolution to a specific local copy of an article, determined by combining the resolution result (several URLs) and local information about the user’s location (from the user’s browser application).

Objects (identified by DOI names) which have common behavior (defined by metadata) can be grouped, using DOI application profiles; these application profiles can in turn be associated with one or more services applicable to that group of DOI names (see Fig. 3).

The Handle System,^[14] the resolution component used in the DOI system, is a general-purpose distributed

information system designed to provide an efficient, extensible, and secure global name service for use on networks such as the Internet. The Handle System includes an open set of protocols, a namespace, and a reference implementation of the protocols. The DOI system is one implementation of the Handle System; hence a DOI name is a “Handle.” DOI names are distinguished from other handles by additional “metadata” and “policy.” The Handle System enables entities to be assigned first-class names, independent of domain names and other location-specific information, which can then be resolved (redirected) to appropriate locations: since the resolution destination is managed and can be changed, this provides a tool for persistence, avoiding “404 not found” and similar problems with URLs. The Handle System is used in a variety of applications such as the Content Object Repository Discovery and Resolution Architecture (CORDRA) of the U.S. Department of Defense (DoD) Advanced Distributed Learning initiative; The Library of Congress National Digital Library Program; and applications in grid computing and advanced future Internet architectures. The Handle System also includes several features not currently used in the DOI system, such as trusted resolution using public key infrastructure.

The Handle System is part of a wider Digital Object Architecture;^[15] that architecture specifically deals only with digital objects with identifiers (Handles). There is no conflict in these two views, since any non-digital entity may be reified (or represented) as a corresponding digital object for the purposes of digital object management

Fig. 1 The role of the DOI system as a persistent identifier. A DOI name (10.1000/123) has been assigned to a content entity; the DOI system provides resolution from that name to a current URL. When the content, previously at URL xyz.com, is moved to a new URL newco.com, a single change in the DOI directory is made: all instances of the DOI name identifying that content (even if already recorded in print, as bookmarks, etc.) will resolve to the new URL, without the user having to take any action or be aware of the change. Note that the DOI name is persistent, i.e., remains unchanged.

Source: From International DOI Foundation.

Fig. 2 Multiple resolution. A Web browser is running an application “Service 1.” That service resolves DOI name 10.1000/123 to the DOI system (1) where it finds four values within the relevant DOI record (2): here, two are of the type URL, one is XML, and one is a conjectural application. Service 1 selects one of these results (in this case, the APP value) on the basis of combining information provided in the resolution result and the local application.

(though some care is needed in the definition of such objects and how they relate to non-digital entities).

METADATA

The object associated with a DOI name is described unambiguously by DOI metadata, based on an extensible data model to support interoperability between DOI applications. Assignment of a DOI name requires the registrant to record metadata describing the object to which the DOI name is being assigned. The metadata describes the object to the degree that is necessary to distinguish it as a separate entity within the DOI system.

A minimum set of such metadata, the DOI kernel, is specified by the IDF. This includes elements such as “other identifier(s) commonly referencing the same referent (e.g., ISBN, ISRC),” and the name by which the referent is usually known (e.g., title). This minimum kernel may be enhanced by registration agencies through the development of specific application profiles with metadata elements appropriate to a particular application or set of applications. The IDF also specifies the template for the exchange of metadata between DOI registration agencies to support their service requirements, and specifies a Data Dictionary as the repository for all data elements and allowed values used in DOI metadata specifications.

The basis of the metadata scheme and extensions used in the DOI system is the index (interoperability of data in

Fig. 3 DOI data model: the Application Profile Framework. DOI names (identifying the entities on the left) are grouped into application profiles. Any single DOI name can be a member of multiple application profiles (e.g., DOI 10.5557/10 is shown here in two). Each application profile can similarly be associated with one or more services: each service can be made available in multiple ways. This makes it possible to make a new service applicable to many DOI names, simply by adding that service to the relevant application profile(s).

Source: From International DOI Foundation.

e-commerce systems) project.^[16] This contextual ontology approach to interoperability is shared by a number of significant content sector activities.^[17,18] This allows the use of a variety of existing metadata schemes with DOI names in a common framework.

The use of these tools for DOI metadata has been limited in initial applications, but more applications are emerging as the sophistication of content management on digital networks and the need for interoperability increases.

SOCIAL INFRASTRUCTURE

DOI names are intended to be persistent identifiers: no time limit for the existence of a DOI name is assumed in any assignment, service, or DOI application. A DOI name and its referent are unaffected by changes in the rights associated with the referent, or changes in the

management responsibility of the referent object. Since such persistence requires a social infrastructure, policies as well as technical infrastructure need to be defined and implemented. The IDF develops and implements policies such as rules for transfer of management responsibility between registration agencies, requirements placed on registration agencies for maintenance of records, default resolution services, and technical infrastructure resilience. These are codified in a formal agreement between the IDF and each of the registration agencies.

The DOI system is not a means of archival preservation of identified entities; it does not store the identified objects themselves; nor does the central DOI Directory store comprehensive metadata (only pointers to the registration agency or other source of such data). The system provides a means to continue interoperability through exchange of meaningful information about identified entities through at minimum persistence of the DOI name and a description of the referent.

HISTORY

The DOI system was the result of a publishing industry initiative in the late 1990s, which recognized the need to uniquely and unambiguously identify content entities, rather than refer to them by locations, and commissioned a study to specify an appropriate technical solution, selected if possible from one or more existing technologies rather than developing a new system. The International DOI Foundation was incorporated in 1998 to develop the system; where possible, existing technologies and standards were adopted for the implementation of the DOI system. The first DOI registration agency began in 2000; by early 2009 around 40 million DOI names had been assigned through eight registration agencies. The most widely known application of the DOI system is the CrossRef cross-publisher citation linking service which allows a researcher link from a reference citation directly to the cited content on another publisher's platform, subject to the target publisher's access control practices. Other applications include government documentation, books, and data; further applications are under development.

The development of the DOI system has proceeded through three parallel tracks:

- An initial implementation of persistent naming: a single redirection from a DOI name to a digital location (URL) of the entity or information about it.
- The development of more sophisticated means of management such as contextual resolution, where the result of a redirection is also a function of some additional information such as local holdings information.
- Collaboration with other standards activities in the further development of tools for managing entities in a digital environment.

The DOI System is a Draft International Standard of ISO, it is expected that the final standard will be published in late 2009 or 2010.

RELATED ACTIVITIES

The DOI system is associated with two independent technical activities which it has used as components of DOI implementations: the Handle System and the series of contextual ontology initiatives derived from the indecs project. Each is used in other non-DOI applications (an aim of the International DOI Foundation was to use existing solutions where available and proven to be useful). Either of these components could be replaced in the DOI system by other technologies offering similar features in the future if necessary.

The International DOI Foundation, particularly through its registration agency CrossRef, has also been closely involved in the development of the OpenURL, a mechanism for transporting metadata and identifiers describing a publication for the purpose of context-sensitive linking. The DOI system is now widely implemented using OpenURL by many libraries: further information on this topic is available from the Crossref Web site. The use of open URL was the first widespread example of more sophisticated means of content management through contextual resolution.

The expertise of the International DOI Foundation in issues such as resolution and semantic interoperability has also led to some IDF members being active participants in discussions of further identifier scheme development such as the International Standard Text Code (ISTC) numbering system for the identification of textual works, and identifiers for parties (persons and organizations), and licenses.

Digital Preservation

Jacob Nadal

ReCAP: The Research Collections and Preservation Consortium, Princeton, New Jersey, U.S.A.

INTRODUCTION

Digital preservation can be viewed as a set of strategies or methods used for preserving information in a certain format and also as a means for preserving information using digital systems. In the first usage, digital preservation is one aspect of preservation writ large, a companion to preservation practices for paper, film, and all the other media of art and expression that libraries collect. In the second usage, digital preservation is closely linked to digitization, the reformatting processes used to create digital surrogates for works that were issued in various nondigital formats. Most professional bodies are careful to make a distinction between digitization as a method of reformatting, and digital preservation, the ensuing process and relevant technologies for keeping the resulting digital content viable over time.

The Association of Library Collections and Technical Services defines digital preservation in process-oriented terms, as the “policies, strategies and actions that ensure access to digital content over time,” focusing on digital collections as objects that require preservation effort and in turn, describing the work that must be done to maintain them.^[1] Libraries have also recognized that digitization and digital libraries can serve as valuable preservation methods themselves. Just as printed books serve to preserve information, but also require libraries to provide preservation support and conservation intervention to keep them usable and available, digital objects can preserve information, provided they are supported by the right systems and practices, and use appropriate technologies to realize the library’s preservation goals.

FRAMEWORKS AND METHODOLOGIES

Digital preservation has developed rapidly, the internet and digital tools themselves providing a platform for the exchange of ideas among practitioners and researchers in libraries and a variety of allied sectors. Even though particular efforts of government or economic boundaries on philanthropy have led to many digital preservation projects, platforms, and technologies that have a strong national or regional association, there are certain frameworks and methodologies that are shared across the globe. These frameworks serve an important role in digital preservation, guiding the development of particular

technologies in the present while also preparing libraries to move from one specific system to another as technologies develop and supersede one another.

The Open Archival Information System Reference Model

The Open Archival Information System Reference Model (OAIS) has achieved near-universal acceptance as the canonical model of a digital preservation system.^[2] The OAIS describes three zones of activity relevant to digital preservation. Although the core of the OAIS addresses management of the archive itself, the framing activities of submission and dissemination are important preservation concepts in the OAIS. In particular, the dissemination activities are coupled to a Designated Community, and the use-cases associated with the Designated Community have a reciprocal effect on the way that the OAIS framework is implemented.

In the OAIS model, preservation begins when Submission Information Packages (SIP) are taken into the archive in a process called Ingest. Ingest associates preservation metadata with the SIP to create an Archival Information Package (AIP). This set of data and metadata is often referred to as a Digital Object among digital preservation practitioners. The core of the OAIS, Management, has two streams of activity. One, roughly analogous to systems administration or core IT activities, is Administration. This set of activities provides archival storage of the AIP, through storage and database maintenance, backup and redundancy measures, and protection of the archive against disasters or threats. The other, Preservation Planning, includes the data management and reporting operations that are necessary to monitor the status of the archive and determine when preservation actions are required, as well as to take in materials from producers and prepare them for the archives as AIPs, and then distribute them to consumers, a process called Dissemination. This involves querying the archive for results sets describing the archive’s contents, and then ordering a Dissemination Information Package (DIP), consisting of some derivative form of the AIP intended for end-users. The DIP could be identical to the AIP, or it could contain alternate versions of the AIP content, perhaps a lower-resolution copy for faster transmission over the network or a version in an alternate file format, when the original format is obsolete.

Deposit Systems for Electronic Publications

Although the OAIS has been accepted as the common reference framework for the digital preservation community in its widest sense, embracing not just libraries, but archives, museums, research centers, and more, the Deposit Systems for Electronic Publications (DSEP) deserves some attention for libraries, specifically.^[3] This model was developed by the Networked European Deposit Library (NEDLIB), one of the host archives for the Portico and JSTOR projects, and reflects an integration of library-specific practice into the OAIS model. Of particular note is the inclusion of numerous sources and recipients for a variety of bibliographic metadata, including publishers and external bibliographic utilities, as well as the relationships mapped between internal preservation functions.

Trustworthy Repositories

The OAIS model is central to ongoing efforts to develop audit and certification processes for trustworthy digital archives. These efforts were initiated in response to an RLG-OCLC report, “Trusted Digital Repositories: Attributes and Responsibilities,” published in 2002.^[4] The audit process couples an assessment of OAIS compatibility with a broader institutional assessment intended to ascertain whether a digital preservation effort has addressed all of the potential hazards in preserving materials, has sufficient technical capability to execute its plans, and has the financial resources and institutional resilience needed to remain in business and capable of responding to future developments. Two prominent efforts that have emerged from the trustworthy repositories: the Trusted Repositories Audit Checklist (TRAC), the related ISO/DIS 16363 standard, and the Trusted Digital Repositories Checklist (TDR).

Program Development

There is an ongoing effort to educate practitioners, so that digital preservation efforts can commence in a variety of institutional contexts. These programs use a variety of frameworks to help practitioners perform needs assessments in order to select appropriate technologies and process changes to advance their digital preservation goals. Where TRAC and related efforts tend to be used for large scale assessments of entire institutions, these program development models can be applied at a small scale, within a single department or subprogram. They share the OAIS reference model as a point of agreement, however, and can be seen as a system of needs assessment aimed toward fuller or improved OAIS compatibility, that might in turn be evaluated or audited through TRAC or TDR.

The longest-standing development program is the Digital Preservation Management (DPM) Workshop, started by Anne R. Kenney and Nancy Y. McGovern with support

from the National Endowment for the Humanities and hosted at Cornell University (2003–2006), the ICPSR (2007–2012), and now at MIT Libraries since 2012.^[5] The DPM model is often described as “Five stages and the Three-legged stool,” for its framework of three categories of activity—policy and planning, technological infrastructure, and content and use—and five stages of program development within them.^[6]

- Acknowledge: Understanding that digital preservation is a local concern
- Act: Initiating digital preservation projects
- Consolidate: Segueing from projects to programs
- Institutionalize: Incorporating the larger environment
- Externalize: Embracing inter-institutional collaboration and dependency

These concepts influence a set of activities hosted by the Library of Congress Office for Strategic Initiatives and funded by the National Digital Information Infrastructure and Preservation Program (NDIIPP). The National Digital Stewardship Alliance (NDSA) and the Digital Preservation Outreach and Education (DPOE) program both promote progressive frameworks, with the assumption that libraries were starting with little or no digital preservation capacity. The NDSA describes four levels of competency in each of five functional areas: (1) storage and geographic location; (2) file fixity and data integrity; (3) information security; (4) metadata; and (5) file formats. The DPOE identifies six core areas of digital preservation activity and trains practitioners to identify, select, store, protect, manage, and provide digital content to their designated communities.

METHODOLOGIES

Digital preservation efforts employ a variety of technical methods to ensure that the data stored in an archive can be rendered in the ways that are useful to the Designated Community. These methods respond to two broad classes of preservation problems: (1) obsolescence and (2) damage. Damage includes any number of events that cause data loss, through failures of media or computing systems; errors in transmission, synchronization, or duplication of data; deliberate sabotage; or a myriad of other possible accidents.

In instances of obsolescence, the bitstream itself may be undamaged, even though the digital object cannot be rendered on a particular system. This is frequently attributed to the changes in the prevailing technologies in use. Examples include the release of a new application software that lacks compatibility with files produced by older versions, file formats that cease to be supported or developed, or broader shifts within an industry or other group from one preferred technology to another.

Bit Preservation

The baseline for all digital preservation efforts is maintaining data integrity. Bit preservation, also referred to as refreshing, uses a variety of approaches to ensure that data are unaltered across time. This includes the maintenance of multiple copies of data so that they can be compared for discrepancies and the periodic copying of data from one physical storage medium to another, to avoid data loss from damaged or decaying media. Bit preservation is usually tested by mathematical derivatives, called checksums or hashes, which can be computed against a particular set of data to show if any bits have changed. A variety of algorithms can be used to compute fixity indicators, but all have in common the property of generating a different value if any bit in the data has altered. Fixity tools do not themselves provide a way to correct damaged data, a process called error-correction. Comparing fixity indicators over time allows digital preservation managers to determine when data were altered and which copies are intact and should be used as the canonical version of the data going forward.

Emulation

Emulation consists in creating a virtual computing system that offers the necessary and significant functions required to execute code from one platform on a different, generally newer and more powerful, platform. Universal Turing machine theory and Moore's law make emulation both possible and practical. All discreet computing systems are logically equivalent, that is, they all perform the same set of logical operations that were initially defined by Alan Turing in his paper "*On Computable Numbers, with an Application to the Entscheidungsproblem*."^[7] This logical equivalency has a valuable practical outcome. Intel founder Gordon Moore observed that improvements in manufacturing were enabling manufacturers to improve the complexity or circuit density of their chips "at a rate of roughly a factor of two per year," effectively doubling the processing power.^[8] Because computer systems have been rapidly increasing in computational power, more recent computers can not only perform every function of an earlier system, as a matter of logical equivalency, but they can also perform those functions at roughly the same speed of the original system.

Emulation has been subjected to some criticism for its apparent complexity, since modeling a physical computer in software is a nontrivial task, and can be more laborious than defining a crosswalk between two formats and writing code to replicate that translation, the strategy used in migration. This potential complexity has been offset in practice by the widespread value derived from emulators. Testing and prototyping of systems and networks in software is much less expensive than doing the same work in hardware for instance, and, because a single emulator can often be reused for many applications, the initial cost of development can be spread over many uses. Emulation has been widely adopted in some areas of digital

preservation, especially for multimedia and interactive systems, such as games and computer art. In these instances, the nature of the work itself requires complex code execution and may also have an important esthetic dimension that could be lost by migration to an alternate format or design.

Migration

Migration addresses the problem of obsolescence by converting from one format or encoding to another. This could mean a change from one file type to another (e.g., migrating an image from TIFF to JPEG2000) or from one method of encoding data to another (e.g., from ASCII text to UTF-8), or both. Migration can be seen as the digital preservation instance of a preservation practice called reformatting, where obsolete or damaged media or formats are transcribed onto or translated into contemporary formats. This approach has the benefit of allowing for easy integration of the resource's informational content into the libraries' current systems and processes. The core disadvantages of migration, as with all reformatting strategies, is that the new format may differ from the original format in ways that preclude certain uses of the information or require additional metadata creation and management to document provenance and significant differences. For many file types or encodings, however, migration is a widely used and easy-to-implement approach to keeping information available.

Forensics and Conservation

In some instances, digital preservation relies on the maintenance of original systems, especially original hardware, to render data. Digital forensics primarily deals with the recovery of data from damaged or obsolete systems, usually by creating a bit-perfect replica of stored data, so that the copy can be examined or altered without risking change to the original. Because the systems in question may be obsolete, digital forensics intersects with conservation through the maintenance of older computing hardware as a means to keep data available. In addition, conservation of computing hardware is done for reasons of material culture preservation, to make the tools and technology of different eras available in present-day curatorial programs or research efforts. Maintaining and repairing these computing systems, as well as the specific knowledge required to use them, mirrors the practices of other branches of conservation practiced in libraries, archives, and museums.

DIGITIZATION

In the late twentieth and early twenty-first century, libraries often centered digital preservation activities around digital libraries created by digitization of their physical resources: (1) books; (2) journals; (3) photographs; and

(4) recorded sound, video, and motion pictures. This focus on digitization as a type of preservation reformatting led to an ongoing emphasis on the creation of high quality digital objects, often referred to as preservation masters. A number of projects exist to promulgate standards for digitization, specifying resolution and bit depth requirements for various media types and desirable formats for storing digital information. In general, these standards emphasized digitization that captures more data than the human eye or ear can perceive, and storing data in file formats that are uncompressed and not encumbered by any proprietary or for cost licenses. These digitization projects tend to be driven by highly specific selection criteria and focus on creating a high-fidelity surrogate of the original items, serving a dual purpose of creating a high-quality preservation master while improving access to library collections, often through curated presentations of materials accompanied by secondary scholarship or other contextual information to create a specific collection in the context of a digital library.

In counterpoint to this approach, a large-scale digitization initiative (LSDI) converts a massive quantity of information into digital forms. Several LSDIs for library print collections were started in the first part of the twenty-first century. The Google Books Project and the Internet Archive's digitization efforts are the largest of these, and were the primary impetus for the creation of the HathiTrust, an organization that operates a preservation repository for the output of LSDI projects and works with its member libraries to develop digital library services and collection management projects built around this corpus of materials. Other LSDI projects are notable, as well, including Microsoft's Live Search and the Million Books Project and, arguably, publisher efforts to convert their catalogs to e-book formats.

BORN-DIGITAL WORKS

Despite the early emphasis on digitization, the largest groups of digital materials in libraries are "born-digital" works. These have no direct analog source, and are often created through entirely digital production processes. The best practice that has emerged for these materials is to accept them as they come to the repository and retain their original format, and then to normalize, migrate, or emulate data and systems to allow access as needed.

Electronic Publications

E-journal preservation is probably the most active area of born-digital preservation, especially when it is combined with e-publications as a whole, including serials, monographs, and published datasets. Libraries subscribe to a large amount of digital content, and have launched cooperative projects to ensure that this content remains available in the future. Although the process and technology

differs between these efforts, they share the common features of a present-day intake mechanism to build an archive, based on an agreement between the publisher and a third-party repository that, in turn, manages permissions based on the subscription profiles of libraries, and provides authorized libraries with post-cancellation access (PCA) to the archive in response to certain trigger events, usually the cessation of business by a publisher or the end of publisher support for a particular title.

Two of the most extensive and long-standing digital preservation efforts have their roots in the e-journal preservation challenge. The oldest of these is called LOCKSS, an acronym for "Lots of Copies Keeps Stuff Safe." This project was started at Stanford University by Victoria Reich and David Rosenthal and has developed into a series of related projects that rely on a peer-to-peer network of many devices to compare multiple instances of a given work and then repair any damage detected. LOCKSS was initially an e-journal preservation effort, but has developed a wider range of services under the auspices of the LOCKSS alliance, including controlled and private LOCKSS systems that allow for the management of a variety of digital content. Portico was also started as an e-journal preservation service, focusing on the content in JSTOR, but has quickly grown by expanding the scope of publishers involved and the types of content maintained in the service. Portico uses a different technical infrastructure than LOCKSS, relying on a smaller number of copies of the entire archive in geographically separated data centers. These mirrors of the archives are in turn monitored for integrity and completeness on a regular cycle.

Institutional Repositories

Institutional repositories have been developed as a way to preserve a variety of born-digital materials, including pre- and post-prints, working papers, student work, ports, datasets, and gray literature. These systems perform the administrative tasks of identifying and documenting works, keeping digital objects organized, and placing objects into reliable storage systems. DSpace, EPrints, BePress, and OPUS were all developed in the late 1990s or early 2000s in close alignment with the Open Access movement, as a way to provide unrestricted online access to peer-reviewed scholarly research. In terms of the OAIS model, these systems control the Ingest, archival management, and dissemination of information. To provide a complete digital preservation solution, they must be connected to reliable archival storage and supported by ongoing preservation management efforts.

Digital art and multimedia works have presented a particular challenge for born-digital preservation, because artworks may be closely tied to obsolescent computing platforms and multimedia works may combine elements with vastly different risks and requirements for preservation. Many preservation efforts in this area focus

on metadata creation to document the as-built state of the work, with the assumption that this will facilitate preservation efforts in the future. Emulation has received substantial attention for this reason, as well, since sufficiently detailed documentation of the system alongside maintenance of its component parts can allow for its emulation on a later computing platform.

Web archiving projects collect websites available over the internet for later access. These efforts face difficulties similar to collecting multimedia work, since the web provides a disparate set of born-digital materials, but the standardizing pressure of network protocols, the HTML specifications, and related technologies mitigates the risks somewhat. Two major difficulties for web archiving are deciding how far to follow hyperlinks in the interest of creating a useful archive, and problems in collecting dynamically generated web pages, since content that is created on the fly from a database or content management system has no single, fixed form that can be treated as a definitive copy of record.

Data management includes elements that align with born-digital preservation, as well. These include the promulgation of standards and the best practices for creating and managing data, which entails making choices about the format and encoding of data and their related rendering software, as well as the creation of metadata that will be needed for the future interpretation and reuse of data. Data management plans are often required by research-funding agencies, and this has led to the creation of tools to assist in data management planning and helped to align data management with related efforts such as institutional repository development.

DIGITAL CURATION AND DIGITAL STEWARDSHIP

The terms “digital curation” and “digital stewardship” have become strongly associated with digital preservation. These ideas place digital preservation within a larger context of selection and appraisal of materials and of providing access to them. These practices are implicit in many digital preservation models, and explicit in others. The OAIS reference model, for example, uses the concept of a Designated Community that receives a DIP as a way of framing access to the archive, and the first two stages of the DPOE model are “identify” and “select,” which focus on determining what content is appropriate for the archive.

The digital curation movement builds on this, however, to encompass many ways of understanding the way technology is used and interpreted in a variety of contexts and to create and manage data in such a way that they can be reused in future research. The Digital Curation Centre, for example, describes eleven steps in their digital curation life cycle,^[9] while the University of North Carolina, Chapel Hill, School of Information and Library Science’s

DigCCurr project proposed 39 elements of “knowledge and competency” in their matrix of digital curation.^[10]

Digital preservation and the core practices associated with it—safe storage, migration, and emulation of data and systems, and forensic and conservation practices—exist as key subsidiary elements of these digital curation models. Digital curation, in turn, is an overarching set of activities that comprise the whole life cycle of materials in libraries and archives, predicated on their continued availability due to sound preservation efforts.

CONCLUSION

Digital Preservation, to borrow the definition of the American Library Association, “combines policies, strategies and actions to ensure access to reformatted and born digital content regardless of the challenges of media failure and technological change.” At present, this area of librarianship is enacted through numerous tools addressed to specific technical issues and a variety of widely accepted frameworks for evaluating preservation efforts and outcomes. In counterpoint to this maturity though, digital preservation efforts are always engaged in adaptation to developments in technology.

Computers and computing have been active fields for decades and if one counts from Turing’s papers, the centenary of digital computing is just a few decades away. In that time, many technologies have proven stable and reliable, but others have been short-lived and problematic from a preservation viewpoint. As of this writing, the text and image data that make up the bulk of library and archive collections are supported by formats and encoding that have been stable for multiple decades, as has digital audio preservation. Video, datasets, and 3-D models all present preservation challenges, however, as do the processes for preserving systems and interactive works, like social media, video games, and websites.

Libraries have adopted, developed, and now depend upon a wide range of technologies, making digital preservation an intrinsic part of library science. Although digital preservation emerged from the problems associated with novel technologies prone to obsolescence, there is substantial evidence of libraries’ success and capability in resolving digital preservation problems, shown by the wide acceptance of certain technologies and frameworks.

ACKNOWLEDGMENTS

I am grateful to the Indiana University Library and their Digital Library Program, where I had my first practical opportunities to work on these issues, and to UCLA and the California Digital Library. I also wish to thank the Library of Congress’ Office of Strategic Initiatives for the opportunities to work on the Digital Preservation

Outreach and Education Program and the National Digital Stewardship Residency, and the Pratt Institute School of Information and Library Science for the opportunity to refine my understanding of preservation by teaching it to smart students. Finally, Anne Kenney, Nancy McGovern, and the Cornell Digital Preservation Management Workshop deserve special recognition for giving me and so many others our first deep dive into the then-new ideas of digital preservation management that underpin much of the work we do today.

Diplomatics

Luciana Duranti

School of Library, Archival and Information Studies, University of British Columbia,
Vancouver, British Columbia, Canada

Abstract

This entry presents the science of diplomatics, briefly describing its history, its theoretical content, and its methodology. Comparing classic diplomatics with modern diplomatics, it discusses the concepts of authenticity, originality, and record. Then, it outlines the building blocks of the diplomatic body of knowledge, that is, the context, the act, the persons, the procedure, the documentary form, and the archival bond and comments on the process of diplomatic criticism and on the usefulness of diplomatics as a discipline.

INTRODUCTION

Diplomatics is a science that was developed in France in the seventeenth century for the purpose of ascertaining the provenance and authenticity of records that attested to patrimonial rights and later grew into a legal, historical, and philological discipline, as it came to be used by lawyers to resolve disputes, by historians to interpret records, and by editors to publish medieval deeds and charters. Its name comes from the Latin term *diploma*—derived from the Greek words διπλω, meaning I fold, and διπλωμα, meaning doubled or folded—which was used in ancient Rome to refer to documents written on two tablets attached with a hinge and later to any recorded deed, and it means “about records.” However, over the centuries, its focus has expanded from its original concern with medieval deeds to an all-encompassing study of any document produced in the usual and ordinary course of activity as a means for it and a residue of it.

This entry briefly outlines the history of diplomatics; presents its purpose, object, and fundamental tenets, including the concepts of record, authenticity, and originality; describes the concepts that constitute the building blocks of diplomatic analysis, including those of person, procedure, and form; and discusses diplomatic methodology and its usefulness. In the process, classic and modern diplomatics will be constantly compared to show their relationship and interplay.

THE HISTORY OF DIPLOMATICS

The history of diplomatics is directly linked to the so-called “diplomatic wars” (*bella diplomatica*), judicial controversies over political or religious claims based on records of disputed origin, which, in the seventeenth century, especially in Germany and France, assumed a

doctrinal character and prepared the ground for a scientific debate between the Benedictines of the Congregation of Saint-Maur in France and the Jesuits organized by Jean Bolland in a scientific society in Antwerp (Bollandists). In 1675, the second volume of the *Acta Sanctorum*, an analysis of the lives of saints published in several tomes by the Bollandists, was released, with an introduction by Daniel Van Papenbroeck, which outlined the general principles and methods for assessing the authenticity of medieval records. In the text, the author, applying his analysis to the records of Frankish kings, declared a diploma issued by Dagobert I to be a forgery, thereby discrediting all Merovingian diplomas, on which most patrimonial rights of the French Benedictines rested.

The Benedictines answered Van Papenbroeck 6 yr later, in 1681, with a treatise in six parts written by Dom Jean Mabillon and called *De Re Diplomatica Libri VI* [¹, p. 37]. The treatise analyzed about 200 documents by comparing the material support, seals, ink, script, punctuation, abbreviations, formulas, discourse, types of subscriptions, etc. and, on the basis of this study, established a method of criticism of records whose validity was recognized throughout Europe. Several works followed Mabillon’s and contributed to a further development of the discipline. Among them, the most notable are the *Nouveau traité de diplomatique* by Rene Prosper Tassin and Charles Toustain, published in Paris between 1750 and 1765, which, by comparing records of different geographical origin, on one hand, demonstrated the validity of diplomatics across contexts and, on the other hand, gave origin to the idea of a special diplomatics for records of the same provenance, and *Beitrag zur Diplomatik I-VIII*, by Theodor von Sickel, in *Sitzungsberichte der Kaiserlichen Akademie der Wissenschaften*, published in Vienna between 1861 and 1882, which linked the assessment of the authenticity of records to the analysis of their procedure of creation. Although mostly regarded as an

auxiliary science of history since the middle of the nineteenth century, diplomatics was included in the body of knowledge required for archivists since the first half of that century in all European archival programs of education and later on in all programs influenced by the European tradition in other continents. As a consequence, diplomatics concepts and methodology became in most parts of the world an integral part of archival science and of the intellectual armor of the archival profession [²], pp. 3–5].

THE OBJECT OF DIPLOMATICS

When discussing diplomatics, it is useful to distinguish “classic diplomatics” from “modern diplomatics,” the reason being that these two branches of the discipline do not represent a natural evolution of the latter from the former, but exist in parallel and focus on different objects of study. Classic diplomatics uses the concepts and methodologies developed by diplomatists living between the seventeenth and the twentieth centuries and studies medieval charters, instruments, and deeds; modern diplomatics has adapted, elaborated, and developed the core concepts and methodology of classic diplomatics in order to study modern and contemporary records of all types. Among the key distinctions between the two branches of the discipline are the concept of record and that of diplomatics. According to classic diplomatics, a record is a document (i.e., information affixed to a medium) that constitutes “the written evidence of a fact having a juridical nature, compiled in compliance with determined forms, which are meant to provide it with full faith and credit” [³], p. 18]. Therefore, classic diplomatics only studies documents that are meant to have legal consequences and therefore require specific documentary forms and is defined as the knowledge of the formal rules that apply to legal records [⁴], p. 1; [⁵], p. 32; [⁶], p. 4]. According to modern diplomatics, a record is a document created (i.e., made or received and set aside for action or reference) in the course of activity as an instrument and by-product of it [⁷], p. 604; [⁸], p. 667]. Therefore, modern diplomatics is concerned with all documents that are created in the course of affairs of any kind and is defined as “the discipline which studies the genesis, forms, and transmission” of records and “their relationship with the facts represented in them and with their creator in order to identify, evaluate, and communicate their true nature” [¹], p. 45; [⁹], p. 28].

THE APPROACH AND PURPOSE OF DIPLOMATICS

Although the primary focus of both classic and modern diplomatics is to assess the trustworthiness of records, the former establishes it retrospectively, looking at

records issued several centuries ago, while the latter is concerned not only with establishing the trustworthiness of existing records but also with ensuring the trustworthiness of records that have yet to be created, thereby taking a prospective approach as well as a retrospective one. Additionally, classic diplomatics identifies trustworthiness with authenticity, while modern diplomatics distinguishes several aspects of trustworthiness. To classic diplomatists, trustworthy records are authentic records, that is, documents “written according to the practice of the time and place indicated in the text, and signed with the name(s) of the person(s) competent to create them” [¹¹], p. 46]. This is far too simplistic a concept for the variety of records that modern diplomatics aims to evaluate and the time span of their creation (from the sixteenth to the twenty-first century), especially in consideration of the fact that its concern is the entire life cycle of records, from creation to permanent preservation. Thus, modern diplomatics defines and assesses four aspects of trustworthiness: reliability, authenticity, accuracy, and authentication.

Reliability

Reliability is the trustworthiness of a record content and is defined as the trustworthiness of a record as a statement of fact. It is assessed on the basis of the *completeness* of the record, that is, the presence of all the formal elements required by the administrative–legal system for that specific record to be capable of achieving the purposes for which it was generated and of the *controls exercised on the process of creation* of the record, among which are included those exercised on the author of the record, who must be the person competent, that is, having the authority and the capacity, to issue it. The reliability of a record is the exclusive responsibility of its creator, that is, of the person or organization that made or received it and maintained it with its other records.

Authenticity

Authenticity is the trustworthiness of a record as a record and is defined as the fact that a record has not been tampered with or corrupted, either accidentally or maliciously. An authentic record is one that preserves the same *identity* it had when first generated and can be presumed or proven to have maintained its *integrity* over time. The identity of a record is constituted of those characteristics that, together, distinguish it from any other record (e.g., the names of its author and its addressee, the date of its compilation, its title, its classification code, or its register number) and is assessed on the basis of the formal elements on the face of the record and/or its attributes, as expressed, for example, in a register entry or as metadata. The integrity of a record is linked to its ability to convey the message it was intended to communicate when

generated. Thus, it does not matter if the ink is fading, the medium (i.e., the material support) is falling apart, or the bit stream is not the same as in the first manifestation of the record, as long as the content is readable and is the same as it was originally intended, the medium does not have missing parts, or the manifestation we see on the computer screen is the same as it was the first time the record was saved. The integrity of a record is inferred not only from its appearance, which might be deceiving in the case of good forgeries, but also from the circumstances of its maintenance and preservation: An unbroken chain of responsible and legitimate custody is considered an insurance of integrity till proof to the contrary. The authenticity of a record is a movable responsibility, as it shifts from the creator, who needs to guarantee it for as long as the record is in its custody, to the preserver, who guarantees it for as long as the record exists.

Accuracy

Accuracy is the trustworthiness of the data (i.e., the smallest meaningful indivisible piece of information) within a record and is defined as their truthfulness, exactness, precision, or completeness and usually presumed for reliable records as well as for authentic records. However, in the digital environment, it is necessary to consider and assess accuracy as a separate quality of a record because of the easiness with which data can be corrupted during transmission across space (between persons and/or systems) and time (when digital systems are upgraded or records are migrated to a new system). Consequently, accuracy also is a shifting responsibility that moves over time from the creator to the preserver.

Authentication

Traditionally, the most trustworthy records are those that are declared to be so by a person who is given such responsibility in a formal way. Authentication is defined as a declaration of authenticity made by a competent officer and consists of a statement or an element, such as a seal, a stamp, or a symbol, added to the record after its completion. It is not to be identified with authenticity—which is a quality of the record that accompanies it for as long as it exists—in that it only guarantees that a record is authentic at one specific moment in time, when the declaration is made or the element is affixed.

STATUS OF TRANSMISSION

Although it is a general assumption that an original record is a trustworthy record, simply because it presents all the possible elements that allow for an assessment of trustworthiness, it is obvious to all diplomatists, classic and modern, that originality has no relationship with

trustworthiness. Rather, it is one of three possible statuses of transmission of a record, that is, it relates to the degree of perfection of a record. An *original record* is the first record generated in a complete form that is capable of reaching the consequences wanted by its author. Thus, an original has the qualities of *primitiveness*, *completeness*, and *effectiveness*. With records that are meant for transmission across space, the original is the document received by the addressee, while with records that are only intended to be transmitted through time (i.e., internal records), the original is the document kept by the author. In the digital environment, the original is the first manifestation of either the received record or the saved record, depending on whether we have an external or an internal record. We have multiple originals when the same record is issued at the same time to multiple recipients, such as a contract (e.g., indenture), a treaty, an invitation, or a directive.

The other two possible statuses of transmission are the *draft* and the *copy*. A draft is a document prepared for purposes of correction and is meant to be provisional, temporary. A draft may have various levels of completion, but it is never an effective or a legal document, and, if kept, it is intended to stay with the author; thus it may be transmitted through time but not across space. If a draft is electronically circulated, the document received by each recipient is an original as to “status of transmission”—having been communicated to an addressee in the intended status of completion and having been the first capable of reaching its purpose of being examined by the person receiving it—and it is a draft only as to content, therefore as type of document (e.g., an ISO draft standard circulated for comments to the ISO members). A copy is a reproduction of another document, which may be an original, a draft, or another copy. Classic diplomatists study the sequence of copies over time to assess the probability of trustworthiness of a text that has been transmitted through the centuries by copying it. The most trustworthy copy is the copy in the form of the original, which is identical to the original in all respects, including holographic signatures, if required, but is issued after the original. Equally trustworthy is the authentic copy, which is declared to conform to the original by an official entrusted with such responsibility. Imitative copies (e.g., photocopies) reproduce both the form and the content of the record; simple copies only transcribe the record content; and inserts (also called *vidimus* or *inspeximus*) are original records containing a copy of another record or a part of it. The study of copies, their process of creation, and their trustworthiness is becoming increasingly relevant in the digital environment as we will no longer have originals on which to assess the authority of records.^[10]

THE BUILDING BLOCKS OF DIPLOMATICS

Diplomatics saw the documentary world as a system and built a system to understand and explain it. Early

diplomatists rationalized, formalized, and universalized document creation by identifying within it the relevant elements, extending their relevance in time and space, eliminating their particularities, and relating the elements to each other and to their ultimate purpose. These elements are building blocks that have an inherent order: in fact, they can be analyzed in sequence from the general to the specific, following a natural method of inquiry [¹¹, p. 107].

The building blocks used by classic diplomatists were the *juridical system*, which is the context of records creation; the *act*, which is the reason for records creation; the *persons*, which are the agents; the *procedures*, which guide the actions and determine their documentary residue; the *documentary form*, which reflects the act and allows it to reach its purpose; and the *archival bond*, which reveals the relationship of a record with all the other records in the same aggregation.

THE CONTEXT OF RECORDS CREATION

As a consequence of its definition of record, classic diplomatics identified the *juridical system* as the only relevant context of records creation and defined it as a social group organized according to shared principles and values that allow it to establish and recognize a body of rules and to give institutions the power to enforce them. Thus, a juridical system is constituted of a community, its institutions, and its legal system. The legal system comprises positive law and all the other conceptions of binding law (e.g., natural law, ethics, custom) that are held by a community.

Modern diplomatics, having extended the concept of record, has redefined the context of records creation as the framework of action in which the record participates and has identified five relevant contexts, proceeding from the general to the specific. They are 1) the juridical-administrative context, that is, the legal and organizational system in which the record-creating body belongs, as indicated by laws, regulations, etc.; 2) the provenancial context, that is, the record-creating body, its mandate, structure, and functions, as indicated in organizational charts, annual reports, the classification scheme, etc.; 3) the procedural context, that is, the business procedure in the course of which the record is created, which, in the modern environment, is often integrated with documentary procedures, as indicated by workflow rules, codes of administrative procedure, classification schemes, etc.; 4) the documentary context, that is, the archival fonds to which the record belongs and its internal structure, as indicated by classification schemes, record inventories, indexes, registers, etc.; and 5) the technological context, that is, the characteristics of the technical components of the record system in which the record is created [¹¹, p. 18].

ACTS

An act is defined as an exercise of will that aims to produce determined effects. Acts are distinguished in mere acts and transaction. Whereas a mere act is an act whose purpose is the accomplishment of the act itself, a transaction is an act that aims to create, modify, maintain, or extinguish relationships between two or more physical or corporate persons. Some acts, especially transactions, occur in writing, thereby resulting in records. Classic diplomatics categorizes those records according to their relationship with the acts that caused their creation. It calls *notitia* a record that was meant to provide evidence of an act that came into existence and was complete before being manifested in writing, while it calls *charta* a record that was meant to put the act into being and was therefore the essence and substance of the act. In modern English, we call the former *probative* records and the latter *dispositive* records. Examples of probative records are certificates, registrations, transcripts, and receipts. Examples of dispositive records are contracts, grants, applications, and money orders. These types of records have all in common the fact that their existence and written form are required by the juridical-administrative system within which they are created, and therefore they are all legal records. They do encompass all the types of documents that classic diplomatics defines as records.

However, modern diplomatics has a much broader focus, and its object of inquiry—what it calls records—is constituted not only of documents whose written form is required, but also of documents whose existence is not required by the juridical-administrative system and the written form of which is discretionary. These nonlegal records can be distinguished in two categories: *supporting* records, whose function is to support the activity in which they take part, and *narrative* records, whose function is one of free-form communication of information. While both categories of records participate in some kind of act, neither is able to provide evidence of such act by itself or to carry it out. Examples of supporting documents are teaching notes and maps, and examples of narrative documents are informal correspondence, discretionary reports, and accounts of events. In the digital environment, two additional categories of records have been identified: *instructive* records and *enabling* records. The former indicate the form in which external data are to be presented (e.g., regulations, manuals of procedure, instructions for filling out forms), and the latter enable performance of artworks (e.g., software patches), execution of business transactions (e.g., interacting business applications), conduct of experiments (e.g., workflows generated and used to carry out the experiment of which it is instrument, by-product, and residue), or analysis of observational data (e.g., interpreting software). The salient characteristic of these two categories of digital records is that the record as it is stored differs from the record as it is manifested on the computer screen [¹⁰, pp. 49–52].

PERSONS

In diplomatics, as well as in law, persons are the subjects of rights and duties, that is, they are entities recognized by the juridical system as capable of acting. This means not only that a person in a given juridical system may not be considered a person in another one but also that the same entity in the same juridical system may be a person with respect to a type of act and not a person with respect to another (e.g., in the past, women have been persons in regard to being paid for a job, but non-persons in regard to owning real estate). Persons can be *physical*, that is, individual human beings, or *juridical*, that is, collections of human beings (e.g., an organization, a committee) or successions of human beings (e.g., a position, a title).

Classic diplomatics posits that, for a record to come into existence, three persons are necessary: the author, the writer, and the addressee. The *author* is the person having the competence (i.e., the authority and the capacity) of issuing a record, which is made by it, in its name, or by its order (e.g., the testator in a last will, the university in a letter of appointment of a professor, the king in a proclamation). The *writer* is the person competent for the articulation of the discourse in the record. It might be the same as the author or may not, as is the case when the author is an abstract entity, such as a corporation. The *addressee* is the person for whom the record is intended in its documentary form. It may coincide with the recipient of the record and may not, as is the case when a second original of a letter of appointment whose addressee is the appointed person is sent to the financial office responsible for paying the salary, which is therefore the recipient.

Modern diplomatics, which tends to focus on aggregations of records, rather than on individual items, identifies a fourth person necessary to the existence of a record, the *creator*, that is, the person in whose fonds or archives a record exists as an item or as part of a file and/or a series. In the digital environment, it is important to identify a fifth person, the *originator*, that is, the person responsible for the electronic account or space in which the record is generated or from which the record is sent ^[12], pp. 51–52]. Persons are the primary diplomatic criterion for determining the public or private nature of a record. Thus, a record is *public* if issued by a public person, that is, a physical or juridical person who, by performing functions considered to be public by the juridical system in which the person acts, is invested with the exercise of some form of sovereignty. A record is *private* when its author is a person “deprived” of public function. In situations in which the wills of a public person and a private person meet in the same record (e.g., a contract between a government and a contractor, or an income tax return), the record acquires the nature of the person who dictates the form and the procedure of creation of the record.

PROCEDURE

A procedure is the formal sequence of steps or phases whereby a transaction is carried out. It is different from a process, which is the series of motions by which a person prepares to carry out the acts involved in a procedure. In relation to each record, classic diplomatics identifies two distinct types of procedures: the procedure governing the act and the procedure governing its documentation. The first type is further distinguished in two categories: the procedures that are the initiative of the persons who carry them out and the procedures that result from an external initiative. The procedures included in the former category consist only of the decisional moment, the *iussio*, while those included in the latter begin with the *petition* to the authority or request to accomplish some action and proceed with the *intercession*, or recommendation of persons close to the authority; the *intervention*, or permission of the persons who are affected by the consequences of the requested action; and the *iussio*, or command to create the record enacting the act or providing evidence of it. After the procedure controlling the action is concluded, the procedure controlling the production of the related documentation begins. Its phases are the *compilation of the draft*; the *preparation of the fair copy*; the unabridged or abridged *registration*; the *validation* through signatures or affixing of stamps, seals, etc.; the *computation of the taxes* for the issuing of the record; and the *delivery* of the record.

Modern diplomatics, having moved the focus of study from medieval to modern and contemporary records, has observed an increasing integration of the procedures for acting and the procedures for creating the record, as over time the acts have begun to be carried out by writing records, and indeed several records for each procedure, not just one, as it used to be. Thus, modern diplomatists have identified for each procedure six typical integrated phases. They are the *initiative*, constituted by the acts that initiate a procedure and producing records such as applications and claims; the *inquiry*, consisting of the collection of the information necessary to evaluate the situation and producing records such as surveys and estimates; the *consultation*, consisting of the collection of opinion and advice based on the information accumulated and producing records such as minutes and discussion papers; the *deliberation*, or final decision-making, resulting in records such as appointments or contracts; the *deliberation control*, exercised by a person different from the author of the record embodying the transaction on the substance and form of the deliberation and the form of the record resulting from it; and the *execution*, constituted by all the actions that give formal character to the transaction and resulting in the final record of the transaction, plus letters of transmissions, registrations, etc. ^[11], pp. 115–119; ^[9], pp. 47–63]. In the digital environment, the same fundamental structure has to date proven to be valid and easy to embed in a workflow.

DOCUMENTARY FORM

Form is the whole of the rules of representation by which an act is documented or a message is conveyed in writing. It comprises all those characteristics of a record that can be separated from the determination of the particular subjects, persons, or places the record is about. The fundamental idea of the early diplomatists was that all records are similar enough that it is possible to conceive of one typical ideal documentary form, a template, which encompasses all the possible characteristics of a record, and which can be used to analyze existing records for the purpose of determining their nature, provenance, and trustworthiness. Thus, they built this ideal documentary form as follows. First they distinguished the formal characteristics that determine the appearance of the record and make it effective from those that represent the articulation of the discourse and make the record complete. They called the former extrinsic elements and the latter intrinsic elements. Classic diplomatics has continued over the past three centuries in this tradition, and modern diplomatics has only introduced a few new elements; therefore, the formal elements of the record are presented here in their logical sequence, with some reflection on their variations over time as appropriate.

Extrinsic Elements of Form

The extrinsic elements of form are the medium, the script, the language, the special signs, the seals, and the annotations. The *medium* is the physical carrier of the record, of which diplomatists study the material, the way it is prepared, the watermark, the shape and size, the edging, rulings, etc. With modern records and the increasing standardization of supporting media, this element has lost importance as it is no longer itself imbued with meaning and a key factor in the assessment of the authority and authenticity of the record. Furthermore, in the digital environment, the medium is no longer to be considered part of the record, although it is still necessary to its existence, as a record that is not affixed to a medium does not exist.

The *script* is not analyzed paleographically, but in terms of layout, paragraphing, punctuation, abbreviations, or initialisms. The *language* is studied in terms of the style, formulas, and tenor of the discourse. *Special signs* are symbols identifying the persons involved with the record, like logos, heraldic images, mottos, stamps, or drawings, and are key to the identification of the record provenance. *Seals* are examined as to their material, size, shape, typology, legend, and the method of affixing or appending them, and they are also indicators of the origin of the record and of its authority.

Annotations are additions made to the record after its completion. They can be distinguished in three types: the annotations that are added to the record at the conclusion

of the procedure generating the record itself, those added to the record in the course of the procedure in which it participates after its creation, and those added to the record in the course of recordkeeping activities. The annotations of the first type, added during the execution phase of the integrated business and documentary procedure, include the mention of the registration of the record in a register or book, with identification of the latter and of the relevant page and date, and the authentication of the record, of signatures on the record, of the identity of persons participating in the issuing of the record, or of the act referred to in the record, such as an oath of office. The annotations of the second type, added in the course of handling the matter in which the record participates, include mention of the decision made or further actions to be carried out, dates of hearings or readings, and locutions such as “urgent” or “bring forward.” The annotations of the third type, added in the course of managing the record, include a registry number, a classification code, and the endorsement of docket-style folded records. In the digital environment, the latter also include the record profile, that is, the metadata schema that is attached to the record for the purposes of declaring and maintaining its identity and protecting its integrity.

Intrinsic Elements of Form

The study of a large number of records of different times and provenance has shown that the intrinsic elements of form, those that are meant to convey the action or message and its context, do not appear in a simple sequence, even if an ordered one, but tend to gather in groups, to be in some relation of subordination to each other, thereby forming sections, each of which comprises several of them [6], p. 527]. Thus, it is fair to say that all records present an ideal structure and an ideal substructure, which is constituted of three sections, each of which has a clear purpose. The first section is called *protocol* and contains the administrative context of the action, that is, the place, date, and subject of the record, and the persons who have participated in its creation; the second section is called *text* and contains the action or message, including its motivation, circumstances, or conditions; and the third section is called *eschatocol* and contains the validation of the record, including the mention of the means used to validate it, the signature of the author, and those of witnesses and countersigners.

The elements that follow will be identified by the English version of their name, except for the few that only exist in medieval records and have retained their Latin name. Classic diplomatists, however, tend to use exclusively the Latin name of the formal elements of records. Thus, for the elements that existed in medieval records, the English name will be accompanied in brackets by its Latin version, as given by the *Encyclopaedia Britannica*^[13].

The intrinsic elements that usually appear in the protocol of a record are the *entitling*, or letterhead, comprising the name, title, capacity, and address of the physical or juridical person issuing the record or of which the author of the document is an agent; the *title* of the record; the *topical date*, that is, the place where the record was issued; the *chronological date* (*actum*, for the date of the act, and *datum*, for the date of the record); the *invocation*, that is, the mention of the entity in whose name the act is made (e.g., God, the Republic, the People, the Law); the *superscription* (*intitulatio*), that is, the name of the author of the record and/or the act; the *inscription* (*inscriptio*), that is, the name of the addressee of the record and/or the act; the *salutation* (*salutatio*), which is usually a formula of greeting; the *subject*, that is, a statement signifying what the record is about; the *formula perpetuitatis*, which is a sentence declaring that the rights given by the record are valid forever (*in perpetuum, ad perpetuam rei memoriam, pp.*); and the *apprecatio*, that is, a prayer for the realization of the content of the record (*feliciter, amen*).

The intrinsic elements that usually appear in the text are the *preamble* (*arenga*), which expresses the ideal motivation of the act or the principles inspiring the message; the *notification* (*promulgatio*), a formula stating that the record is communicated to all those concerned, who therefore must be aware of it; the *exposition* (*narratio*), which explains the concrete circumstances and motivation for the creation of the record; the *disposition* (*dispositio*), that is, the act or message that the record is intended to carry out or convey; and various *clauses* expressing the obligation of those concerned to respect the will of the author (*of injunction*), the prohibition to violate the act or oppose it (*of prohibition*), the obligation to respect the act notwithstanding other orders or decisions contrary to it (*of derogation*), situations or conditions that constitute exceptions (*of exception*), the obligation to respect the act for one's heirs or successors (*of obligation*), the consent to give up a right or a claim (*of renunciation*), a threat of punishment should the act be violated (*of warning* or *sanctio*), or the promise of a prize (*promissory*). Sometimes the *apprecatio* concludes the text, or begins the eschatocol.

The intrinsic elements that usually appear in the eschatocol are the *corroboration* (*corroboratio*), a clause that states the means used to validate the record (e.g., "signed and sealed," or "I have hereunto set my Hand and Seal of Office"), normally followed by the topical and chronological date; the *complimentary clause*, which is a brief formula expressing respect (e.g., "Yours truly"); the *attestation* (*subscriptio*), that is, the subscription of those who took part in the issuing of the record (author, writer, countersigner) or of witnesses to the enactment or to the subscription; the *qualification of signature*, that is, the mention of the title and capacity of each signer; and the *secretarial notes*, such as initials of the secretary, indication of enclosures, or indication of additional recipients of the record.

ARCHIVAL BOND

The concept of archival bond is unknown to classic diplomatics because of its focus on medieval records, the main characteristic of which was the fact that each incorporated the entire act as carried out through the acting procedure and the subsequent documentary procedure. The focus of modern diplomatics on modern records meant that one of its main concerns had to be the interrelationship that each modern record has with the previous and subsequent records that participate in the same act and/or integrated business and documentary procedure. This interrelationship, following archival theory, was by modern diplomats called the archival bond and was configured as an incremental network of relationships that links all the records of the same file and/or the same series and the same archival fonds. The archival bond is *originary*, that is, it exists from the moment a record is created; *necessary*, that is, there is no record without it; and *determined*, that is, uniquely defined by the function of the record in the business activity in which it participates. Besides determining the whole structure of the archival fonds, the archival bond is the primary identifier of each modern record and is usually made explicit by a classification code. While in a traditional paper environment the archival bond is implicit in the physical location of the record in the aggregation in which it belongs, in the digital environment it must be made explicit and expressed among the metadata; otherwise, according to the archival postulate that a record is made up of a document and the whole of its relationship, we are unable not only to identify the record but to have a record altogether [¹², pp. 53–54].

DIPLOMATIC CRITICISM

The structure of diplomatic analysis, or criticism, as it is called by classic diplomatists, is rigorous and systematic and may proceed from the general to the specific or vice versa, depending on the available information. The early diplomatists first separated the record from the world and then put them into relation trying to understand the world through the record. Thus, they began analyzing the formal elements of the records, and, from the results of such analysis, they reached conclusions about procedures, persons, acts, and contexts. They firmly believed in the possibility of discovering a consistent, underlying truth about the nature of a record and of the act producing it through the use of a scientific method for analyzing its various components.

The diplomatic analysis of the elements of a record is a process of abstraction and systematization, the aim of which is to identify the essential attributes of a record and make them transportable to different historical and documentary contexts. By decontextualizing and generalizing the essential attributes of a record, the original

diplomatists were able to recognize and evaluate records created over several centuries and across different juridical systems. The overarching thesis of contemporary archival diplomatics is that it will enable archivists to recognize and identify electronic records created in a variety of administrative contexts and in different hardware and software environments [¹⁴], p. 209].

Indeed, modern diplomatics has gone much further than that: Using its century-old understanding of the nature of records and of their necessary characteristics, it has attempted to design record-making and recordkeeping systems and to determine at the outset the documentary form of the records resulting from specific acts. This proactive stance is still experimental and it has mostly been developed in the course of two research endeavors called “The UBC Project” and InterPARES [¹⁴], p. 199]. However, irrespective of its success as a designing instrument, diplomatics remains a fundamental component of the intellectual armor of every record professional.

Diplomatics has long been recognized as a formative discipline, which develops analytical ability by making explicit the set of principles by which a record is created, and its form is shaped by defining its elements by their meaning and function, their order, and their consequences and by naming them in a consistent and meaningful way. In addition, it enables record professionals to work with a heuristic device, a diagnostic tool for establishing the meaning of the phenomenon under investigation, thereby making possible the understanding of unprecedented manifestations of records, the assessment of the trustworthiness of records that come to us at the end of several reproduction processes (in this regard, it is complementary to Digital Records Forensics [¹⁵]), and the identification of what needs to be protected and how to ensure that a trace of our actions will be carried into the future. Finally, the capacity of diplomatic analysis to uncover the interrelationships of records focusing on context over content and on purpose over use makes of it the most useful instrument for carrying out all archival functions, from appraisal to arrangement and description and from preservation to communication.

CONCLUSION

This entry has outlined the origin, purpose, object, and content of a three-century-old science, diplomatics, which has been used by several disciplines—such as jurisprudence, philology, history, and archival science—primarily, as an instrument of inquiry, a tool for analysis, but which has a substantial body of knowledge of its own, especially in its conceptualization of the record, and should be studied on its own merit by all those who either manage records or use them as sources.

The discussion of the concepts has been carried out comparing the perspective of classic and modern

diplomatics. The reason is that modern diplomatics does not replace classic diplomatics but adapts and elaborates the same body of core knowledge to make it applicable to modern records. Thus, we have two branches of one science that coexist and are equally important. While classic diplomatists, being persons of our times, need to gain an understanding of contemporary records by accepting modern diplomatics, modern diplomatists could never grasp the depth of diplomatic concepts without learning first classic diplomatics. The profound understanding of the nature of records that both classic and modern diplomatics provide is a vital component of the intellectual armor of every record professional and, like in Europe, it should be an integral part the curricula of graduate education for all records, archives, and information specialists.

Abstract

Disaster planning is the ongoing process by which cultural institutions (libraries, museums, archives, etc.) seek to prevent loss of collections using data gathered to identify and mitigate risks; prepare and revise the written Disaster Plan; and train staff in response procedures.

This entry briefly discusses disasters of the last few decades, which have led to today's understanding of disaster planning. The majority of the text discusses the major components of a disaster plan and the requisite steps for achieving an effective plan.

DISASTER-DRIVEN: HOW DISASTERS HAVE LED TO IMPROVEMENTS IN DISASTER PLANNING

Disasters to repositories of cultural materials (libraries, museums, etc.) have always happened. Acts of nature and of man have taken their toll ever since man assembled the first collection—each loss resulted in an irreplaceable loss of cultural memory.

Thus, it is surprising that it was not until the mid-twentieth century that disaster planning and prevention efforts by libraries and other cultural institutions gained momentum.

The beginnings of modern disaster planning for cultural institutions can be traced to the 1966 flooding of Florence, Italy when the Arno River rose 22 ft, covering millions of books, manuscripts, and works of art in water, mud, oil, and sewage in numerous libraries, churches, archives, and rare bookshops. Conservators from all over the world sped to aid these institutions. The Florence flood heightened awareness of the incalculable loss that major disasters can inflict upon the world's cultural legacy and the enormous resources needed to recover from them.

In the months and years following the Florence flood, much was learned about how to effectively treat wet materials. For example, when the disaster first happened, freezing was not accepted nor was there sufficient technical support to use it as a means of preventing mold growth and stabilizing the materials. But by the 1990s freezing most materials, to buy time, had become the first step in recovering water damaged collections. Through the cooperative efforts of conservators, and many others from all over the world, major improvements to conserving and restoring wet objects were made. British conservator Peter

Waters (later head of the Library of Congress' Preservation Office), who worked on-site in Italy, drew on his experiences in his *Procedures for Salvage of Water Damaged Library Materials*,^[1] a preservation resource which is still highly regarded today. Hilda Bohem's 1978 work, *Disaster Prevention and Disaster Preparedness*^[2] was the first to describe the elements of a disaster plan and how an institution might organize the work to achieve it.

A few examples of some of the advances in response and recovery that have come out of experiencing disasters follow.

Water Damage

While the Florence flood taught much about cleaning and air drying wet materials, in the late 1970s, speculation began on how to dry large quantities of objects more efficiently. Options for drying treatments that would not distort the materials, especially when large quantities were involved, were extremely limited. However, following the Stanford University Library Flood, in 1979, vacuum freeze-drying was used for the first time and eventually became the preferred method to dry paper, especially for books printed on coated paper. Although the vacuum freeze-drying process is still undergoing refinement, there is no doubt that it has saved numerous collections from irretrievable loss. Other mass drying methods such as freeze-drying (done with heat) and dehumidification are used to a lesser extent.

In 2000, the European Space Agency (ESA) began to offer satellite images of environmental disasters in Europe adding a new source of information on the extent of damage from natural disasters.^[3] In 2002, the waters of the

Elbe rose to record highs affecting primarily Germany, Austria, and the Czech Republic. Early warnings allowed for evacuation of some cultural artifacts in Prague and Dresden^[4] but, “in general the water was just too high for all materials to be moved... a number of libraries, archives, and art museums had their basements and ground floor completely flooded. . . It is estimated that one million volumes were under water, 800,000 in the Czech Republic alone and the majority of them are lost.”^[5] The Elbe River rose to record high level’s again in Northern Germany in 2006.

Earthquakes

Understanding how to withstand sudden and unpredictable earthquake damage to buildings which house collections is a significant challenge to cultural stewards, architects, engineers, geologists, contractors, and first responders (personnel trained to react to emergencies such as: firemen, police, and facilities staff).

In earthquake-prone California, the California State Library recommended seismic safety standards for library shelving due, in part, to the effects of the 1971 San Fernando earthquake (6.6 on the Richter scale) which included the collapse of a hospital which had just been built as “earthquake resistant.”^[6]

In 1989, an earthquake of 6.9 was centered near the Loma Prieta peak in the Santa Cruz, California mountains, approximately 14 km (9 mi) northeast of Santa Cruz and 96 km (60 mi) south-southeast of San Francisco.^[7] The unbraced stacks of the University of California campus library located there collapsed. In 1990 and again in 1991,

other southern California cultural institutions whose stacks and storage areas were seismically braced proved that the bracing standards needed improvement (see Fig. 1).^[8] [See also Library Stacks and Shelving, created by Earl Siems and Linda Demmers and provided through the Libris Design Project (<http://www.librisdesign.org>), <http://www.librisdesign.org/docs/ShelvingforLibraries.pdf> (accessed May 2008).] Subsequently new standards were adopted by the *Uniform Building Code-California Additions*.

The fact that properly braced shelving can survive was borne out in the earthquake that devastated the California State University, Northridge, January 1994. Even though 600,000 books required reshelving, this process was less costly in terms of time and money than replacing broken shelving as had been the case following the San Fernando quake. While anticipated damage to structural concrete, drywall and nonstructural ceiling tiles occurred, the Northridge calamity provided an unexpected education on steel frame buildings. Construction with steel framing to withstand earthquakes did not work in this case. The four-story high girders in the library’s wings cracked at the 4 ft thick steel base fastened to the foundation. Microform storage units also proved dangerous, resulting in the cabinets shifting and falling over and the self-locking drawers opening from the force of the ground swell. This led to new recommendations on seismic retrofitting to fasten cabinets to walls and each other.

Fires

Similar to seismic and structural guidelines, fire safety is also covered by a variety of building codes^[9] and the

Fig. 1 Failed seismic bracing.

National Fire Protection Association.^[10] Concern for having fire codes rose to a panic level in the nineteenth century following the Chicago Fire and other tragedies and ultimately led to improved codes for building materials.

Fire resulting from defective electrical, heating, or photocopying machines, arson, construction, lightening, and other causes is still a prime threat to all cultural institutions; as is the combustion level of historic buildings. For many years there were debates about the destructive power and incinerating effects of fire and heat versus, the damaging effects of water used to arrest the spread of fire and the accompanying smoke damage.

The fire detection and suppression industry, however, has adhered to rigorous standards and in doing so has made strides to improve the precision and timeliness of detecting fires and alerting potential victims and responders. Most of this progress is a result of new technology such as fine mist sprayers. Advances in technology have also led to fewer instances of indiscriminate and inadvertent release of water from sprinkler systems, and the availability of a number of choices for water delivery. When appropriate fire suppression is employed, results can be positive as illustrated by the Historic Fourth Ward School Museum fire on February, 2008 in Virginia City, Nevada. In that case, the 20 year old sprinkler system saved the building and minimized damage to the collection.^[11]

The Los Angeles Central Library arson fire of 1986 also demonstrated the importance of fire detection and suppression. An effective smoke alarm system and evacuation procedures saved staff and patrons. However, the lack of a sprinkler system and fire doors, combined with an open flue-like stacks configuration of the old Carnegie building resulted in \$18 million worth of damage and destruction to the collection (400,000 books burned and 500,000 were damaged by heat and smoke).

In 1988, the damages from a fire at the Academy of Sciences Library in Leningrad, Russia surpassed those of the Los Angeles Public Library. Again, 400,000 books were destroyed by fire but an additional 2–3 million were damaged by heat and smoke, and 1 million items were damp and wet. In this case, the library had no disaster plan or, it seems, any other type of preparation. While at first the authorities tried to suppress information and minimize reports of damage, eventually, they invited consultants from the Los Angeles Library fire and other countries for advisement.

An article in the 1991 *Book and Paper Group Annual* reports on the progress of the recovery and the many techniques tried and some promising new techniques developed.^[12]

Useful Tool: Barclay Ogden's 2004 publication, *Collection Preservation in Library Building Design*, does an excellent job of incorporating preservation and disaster concerns in building design and interior space intended to minimize risk and harm.^[13]

Civil Unrest, Armed Conflicts

Three sets of international treaties form the framework for protecting cultural heritage in time of war and its aftermath. These are The Hague Conventions of 1899 and 1907; the Geneva Convention of 1949 and its two Protocols; and the Hague Convention of 1954 and its two Protocols. Together, they respond to four threats to cultural heritage: deliberate attack, incidental damage, pilage, and outright theft.^[14]

Museums, libraries, and archives are particularly vulnerable in times of armed conflict. With the culminating recognition that cultural property was entitled to protection from outright acts of war and associated risks, a treaty to address the protection of both moveable and immovable cultural property was realized in "The 1954 Hague Convention on the Protection of Cultural Property in the Event of Armed Conflict" developed under the auspices of the United Nations Educational Scientific and Cultural Organization (UNESCO). This convention was strengthened in 1999 with the issuing of the "Second Protocol" particularly in the recognition of explicit crimes in relation to breaches of cultural protection and permanent institutional arrangements including meetings and an elected Committee. Moreover, the International Committee of the Blue Shield was established in 1996 to work to protect the world's cultural heritage threatened by wars and natural disasters, and its constituent "civil" organizations have standing advisory roles in relation to The Hague's Committee. In addition to The Hague Convention, other international conventions address terrorism and the illicit traffic of cultural property. Sadly, the world continues to witness the threat to institutions from civil wars, ethnic conflicts, and terrorism as demonstrated in Iraq, Croatia, Bosnia, and elsewhere.

Avoiding all disasters is impossible because there will always be hurricanes, floods, fires, and wars. However, being prepared with a plan is crucial to ensuring optimal response. Disaster planning today goes beyond the preparations that individual institutions make, and includes collaborative planning on local, regional, national, or even international levels as The Hague Convention advises. A significant event can serve as the catalyst for developing cooperative emergency preparedness networks. Such was the case in the devastating Los Angeles Central Library fire in 1986 that inspired formation of the Inland Empire Libraries Disaster Response Network in southern California, which in turn led to similar networks in California and elsewhere. Similarly, the Heritage Emergency National Task Force—Alliance for Response^[15] initiative builds partnerships in cities across the United States between cultural heritage stewards and first responders to help emerging networks become cooperative models. The Task Force's "Lessons Applied"^[16] initiative assists members with developing and implementing projects to address issues raised by hurricane Katrina in 2005, and provide tools useful for disaster planning.

Since Italy's 1966 flood, the concept of disaster planning has broadened to include all stages of planning and preparation. Cultural stewards are making better use of expertise and practices from other industries and occupations, and more cooperation is in evidence between those responsible for heritage collections and emergency management professionals. In addition, professional recovery services with experience in libraries, archives, and museums are more widely available as well as national and international preservation initiatives and collaborations have increased.^[17]

ACHIEVING A DISASTER PLAN AND A PREPARED STAFF

It is a common axiom that disasters only occur on holidays, evenings, and weekends and one might add "when under construction." This refinement of the Murphy's Law adage should be firmly in mind when preparing the disaster plan and when training staff.

The purpose of this section is to highlight important preliminary steps in disaster preparedness, such as risk assessment and mitigation, collections assessment, and setting collections priorities. We also discuss several basic components of a typical disaster plan, such as: packing out instructions; insurance considerations; staff training; response actions; salvaging, building concerns and the like from other countries.

The goal of a disaster response strategy is to plan for and ensure the protection and/or salvaging of collections. A well-conceived disaster plan replaces chaos with thoughtful, deliberate response and recovery guidelines. In doing so, it increases the speed and efficiency of response, while minimizing damage, saving money, and decreasing the amount of time service is disrupted. While institutions always hope such a plan will never be necessary, advance preparation for a disaster is an inexpensive form of insurance when compared with the daunting challenge of salvaging and—if even possible—replacing huge segments of the collection.

While a written disaster plan is important, the need to familiarize staff with these guidelines, and train them in response tactics cannot be stressed enough. When disasters strike, time is critical; therefore having both a plan of action and first responders who are trained and prepared to jump into action is much more efficient than trying to bring them up to speed while dealing with threats to the collections.

Whatever the size or manifestation of a disaster, keepers of cultural heritage have learned that no institution is immune. They have also learned that emergencies of any size may result in the disruption of services, as well as a loss to cultural memory. Most importantly, experiences have taught that preparation, by way of an organized and coordinated response strategy, is essential.

The first activity in developing a plan is to gather information on an institution's current risks.

Useful Tools: dPlan, a free online disaster writing template is posted on the Northeast Document Conservation Center (NEDCC) Web-site (<http://www.dplan.org/aboutdplan.asp>):

Enter information about the institution using the comprehensive fill-in-the-blank template. The template guides the writer through the steps necessary for effective disaster planning. Once completed, dPlan generates a printed disaster plan specific to the institution. The resulting plan contains contact information for staff and key personnel, preventive maintenance checklists, salvage techniques, and much more. dPlan can be updated continuously to reflect the changes that occur.^[18]

Conservation OnLine (CoOL) is a great tool for all areas of preservation and conservation. Its "Disaster Planning and Response" section has good examples of disaster plans that can be used as models. <http://palimpsest.stanford.edu/bytopic/disasters/>.^[19]

Assessment of Risks

Before an institution can successfully articulate preventive measures, the hazards and/or situations that are potentially damaging to collections must be identified.

As mentioned earlier, emergency situations often result from a combination of forces including natural and/or man-made threats, faulty mechanical systems, weakened physical storage structures, and the collections themselves (such as nitrate negatives). The most effective method of minimizing or, even better, eliminating these risks is through a comprehensive risk survey. This important first step in long-term planning and preventive maintenance includes close examination of geographic, climatic, structural, and interior hazards that pose potential threats to cultural collections. For example, is the building susceptible to damage from natural disasters such as hurricanes, tornadoes, or earthquakes? Or, is it located in a flood plain? Does the structure have a flat roof or a very old roof? Basically, the comprehensive risk assessment requires a thorough survey of both the exterior of the storage facility as well as the interior's structural and nonstructural elements.

When surveying the interior of the building note the availability and location of fire suppression systems, alarm systems, water sources and the condition of plumbing. Consider past events. Where have there been problems in the past and what caused them? Is there a bathroom with constant plumbing problems or a leaky air conditioner? Shelving for the collections is also important and must be examined for location and stability.

Ultimately, the risk assessment seeks to provide the best possible picture of exactly what hazards may threaten the storage facility, and the collections they house.

Prevention/Mitigation

Once the data has been collected and analyzed, strategies to mitigate the potential risks need to be mapped out. Some hazards may be minimized or prevented by the facilities staff doing regular building inspection (e.g., clean leaves from gutters and check drainage around building in fall and spring). Certain “fixes” may require more labor-intensive or costly strategies (such as a new roof or a new heating, ventilation, air conditioning (HVAC) system). If, however, “all improvements cannot be undertaken at once, make a schedule and follow it.”^[20] In the meantime, list the actions that should be taken when there is a threat (i.e., when a storm is predicted put plastic sheeting over objects and shelving areas where the roof is known to leak). Regular inspections will catch new problems before they become hazardous.

Preparation Activities

The purpose of this set of activities is to gather information which results in documentation, instructions, policies and procedures, and assigning responsibilities; each of which become part of the Disaster Plan.

Assessing collections assets and setting priorities

If the entire building was under water and everything in it was wet, what assets should be saved first? This is one eye-opening approach to establishing salvage priorities.

When responding to disasters, working quickly will lessen damage; therefore, immediate access to information that articulates what item(s) or collection(s) to salvage first is critical to a successful recovery. Determining collection salvage priorities during the Preparation phase can save valuable time during an emergency situation.

Normally, priority for salvage is given to those records and collections that are not backed up elsewhere and (1) have information needed to either establish or continue operations, including administrative records necessary to pay staff, responders, and vendors; (2) have the highest value; and (3) assist in fulfilling the requirements of the insurance company in order to file a claim. Early determination of salvage priorities save valuable time during an emergency situation and should therefore should be done early in the Preparation process.

What is the emphasis of the collection? What is the greatest current need to support the institution’s programs? How difficult is the material to replace and/or how costly? What type of formats are included in the collections, and to what are they most vulnerable? Can the material be frozen? Can it be air-dried? Knowledge of this information may change its priority on the list. Being aware of the vulnerability of the collections’ format is important, and may result in moving some collections to a higher priority. An excellent document to both assist

with prioritizing and to place in the disaster plan is “Salvage at a Glance” by Betty Walsh.^[21]

The highest priority collections will be the first items packed out if they are damaged or the threat of damage is imminent. If these items are not in immediate danger, or are impossible or too dangerous to reach, then the next highest priority would become the focus for salvage. Consider the circumstances and limiting factors (time, access to materials, availability of resources, etc.) which may require deviations from the plan.

In large institutions, especially libraries, priorities are usually assessed by groups of materials or subject classification rather than item-by-item. Individual items which have extremely high value might, however, be listed separately. One thing is certain: running around a building during the crisis, gathering an item here and there is an inefficient way to salvage any collection.

Instead, salvage priorities should be documented and added to the Disaster Plan. In addition, the location of high priority items and/or collections should be clearly marked on the Floor Maps used by staff and other rescue workers.

Pack-out instructions

What will be the packing techniques to remove items from the building safely? Having just determined the salvage priorities, this is an opportune time to proceed with developing instructions on how to safely pack-out the different formats, whether wet or dry. Will there be a staging area to transport the material to or will the wet items be so delicate that they must be packed in place rather than handled a second time? With large-scale book disasters, packing books into boxes often happens right in the book stack aisles where the only sorting is between wet and dry. Other times a staging area is set up and the books are brought to it on book carts where they are sorted by wet, damp, and dry; might have freezer paper placed around every other or every one; and where more precise inventory control can be carried out. These instructions are added to the Disaster Plan.

Staff training

Staff training has already been mentioned a few times in this entry and its importance cannot be overstated. Clarifying roles and responsibilities and periodically practicing salvage techniques gives staff confidence and teaches success. Training can also reveal weaknesses in the Disaster Plan. Are there gaps in resources, for example? Does communication and coordination need improvement? Do staff members know the chain of command and have copies of contact lists? Do they even know where to find a copy of the Disaster Plan?

Training exercises should be as realistic as possible. Wet materials are extremely fragile so all staff should be given hands-on experience with carrying and packing all

the major formats collected by the institution. Libraries, which regularly deaccession books, can provide a ready resource for experimentation and training. Deaccessioned items can be wet in order to train staff in the proper way to remove materials from a shelf and how to box them. This exercise can be paired with having each staff member take a wet book and learning to air-dry it.

One way to teach damage assessment is to design a scenario that simulates wet and/or fire damaged material in storage areas. This can be signaled easily with crepe paper streamers (e.g. black crepe for burned; blue for wet books). Have the assessment teams take pictures, mark damage on the floor maps and estimate the number of damaged items.

Other exercises may be done sitting around a table and describing a situation and walking it through with the Disaster Plan.

It is good to work with local emergency responders involving them in drills and training whenever possible. Making them aware of the salvage priorities as well as walking them through the building is also a good preparation step.

Useful Tools: *The California Preservation Program has a Web site with several useful documents in the section on "Emergencies Preparedness and Response." In addition to an elaborate tabletop exercise there is a "fill-in-the-blank" disaster plan workbook and templates* (<http://calpreservation.org/disasters/index.html>).^[22]

Supplies, suppliers, service vendors, and consultants

The Preparation phase is a great time to purchase and distribute supplies to have on hand to aid in immediate response for small and moderate disasters, and to also list the response supplies and equipment in the building. Compile contact lists of suppliers and vendors in the surrounding area who would be able to provide the amount of supplies necessary to respond to any large size disaster. Another important contact list to generate is for disaster services vendors as well as recovery and conservation experts. These lists of in-house supplies and equipment, suppliers and vendors, and potential consultants are invaluable components of the Disaster Plan. The locations of in-house supplies should be clearly marked on the Floor Maps.

Useful Tool: *A useful Web site to consult for supplies, suppliers, and experts is The Disaster Mitigation Planning Assistance Web site* (<http://matrix.msu.edu/~disaster/>).^[23]

Finances

Procedures on accessing funds and finances should be added to the Disaster Plan. One of the many roadblocks that can slow down recovery is how does the institution pay for what is needed? While an important part of being prepared is to buy and store supplies before they are needed the amounts are limited by the building's capacity

to store them. In most cases, the supplies in storage would be expended quickly in a major disaster. Another example: workers must be fed regularly and take-out restaurants are unlikely to accept institutional purchase orders. Thus, the cash on hand at the institution on an average day should be taken into consideration. Are there institutional credit cards and, if so, who is authorized to use them? Can purchase order information be set up with local vendors ahead of an event? If staff members pay for something related to the recovery, how quickly can they be reimbursed?

Insurance

Another area that must be investigated during the Planning or Preparation Phase is the insurance policy. Find out how the institution contents are insured and learn the policy's exclusions. Meet with the risk manager and/or insurance representative to review coverage and discuss the documentation required to file a claim. What is the replacement cost per book or per object? What documentation does the insurer require in order for the institution to begin salvage efforts immediately without waiting for a company representative? For rare and valuable items a special policy, often called a "fine arts" insurance policy, covers each piece individually against all risks. This list must be updated annually and the items should be given a high salvage priority.

Once the information is gathered, develop a document for the Disaster Plan that succinctly gives instructions on how to file a claim. In addition, the contact information for the insurance company is added to the appropriate contact list in the Disaster Action Plan. Claim forms and instructions can become one of the plan's appendices.

Note about FEMA: Federal Emergency Management Association funds are difficult to get. It pays, therefore, to file as soon as possible, document everything and take extensive pictures.

Chain of command, communication, and contact information

There are many steps needed to achieve a successful recovery from a disaster. The most important may be in the assigning of responsibilities and ensuring those duties are clearly understood and practiced *before* an emergency occurs. Setting up a clear chain of command and reporting relationships that are understood by all staff is particularly essential.

In the Planning and Preparation phases, staff members' roles during disaster response and recovery should be clearly defined and extensive training implemented in order to teach them how to fulfill their responsibilities. The Appendix lists many of the tasks that need to be assigned for a successful response and recovery. It pays to assign each responsibility to the appropriate staff

member. For example, a cataloger might be assigned to maintain inventory control, and track the materials either moved to other sites or sent to commercial drying companies. Once these roles are assigned, the next step is to put the information in writing and compile the contact lists that are needed for the Response section of the Disaster Plan.

Upper management level staffs, together with certain additions such as the facilities manager, preservation specialist, personnel representative, and budget/finance person oversee the entire Response and Recovery phases. Once called to report to the Command Center (a group of individual staff members who have been assigned key responsibilities in responding to disaster) each member assumes his or her role as operations director, recovery coordinator, risk management/insurance, finance person, personnel, public relations and communications, facilities, disaster coordinator, etc (see Appendix).

The next level of staff consists of the individuals who have been designated and trained to deal with a disaster of any type. This group is often called the “Disaster Response Team” or “Disaster Action Team” and may include some members of the Command Center Team as well as department heads and supervisors. The primary purpose of this group is to deal with the day-to-day issues of getting the work done, such as leading work teams in packing out, monitoring supplies, inventory control, and training other staff members and volunteers in proper salvage procedures.

Remaining staff make up the disaster work teams, or if physically unable to do the packing out duties, they help with inventory control, phone calls, refreshments, screening volunteers, etc.

Useful Tool: *The Council of State Archivists (CoSA) has developed a “Pocket Response Plan (PReP)” one side of which is an Emergency Communication Directory, with contact information for staff, first responders, emergency services, utilities, vendors and suppliers, disaster teams, etc. The other side contains an Emergency Response and Checklist for Collections Recovery that lists actions that should be taken in the first 24–72 hr following a disaster.*^[24]

Management issues

To manage a disaster response and recovery operation effectively requires access to a variety of ways to communicate including cell phones, walkie-talkies, e-mail, and even people to serve as “runners.” While remaining on-site is the best option for the Command Center Team to manage the operations and may also be the best psychologically for the staff, it can be a problem if electricity is not available. Ideally, several areas within the building will have been planned to become the designated Command Center, and hopefully one of them is actually accessible and has electricity. If this is not possible, the institution should consider renting a modular unit with a

generator parked near the building or space in a nearby building.

Other areas that should be identified before they are needed are those areas in the building that could serve as staging areas to triage materials and properly pack items being sent out of the building.

Among the many other duties, someone, on the Command Center Team should have responsibility for keeping staff informed of progress, perhaps with briefings at the beginning of shifts or as staff exit and enter the operation. Even if it is only a series of handwritten notes posted and updated regularly, it will reduce the sense of isolation that staff feel when working “in the trenches.”

A brief description of the responsibilities, along with contact information for the person assigned to them, should be documented and added to the Response section of the Disaster Plan. Any contact list should list all the ways each person (staff, vendor, suppliers, custodians, safety, etc.) can be reached, including on evenings, weekends, and holidays.

Another vital contact list is the “First Response Emergency Contact List.” As any staff member might be the person who discovers an emergency situation; he or she needs to know how to respond. A brief set of instructions to ensure the staff member’s safety and a short list of whom to call to report the problem needs to be assembled. These instructions should be given to every staff member, and posted by every work phone. To be truly effective this document will need to be reviewed and updated on a regular basis and, similarly, staff members should be reminded of its existence every few months.

After identifying the nature of the emergency, the person who discovers it should be able to determine what type of emergency responder is needed. In other words, is this something that may easily be handled by custodial staff, or should they call either the fire or police departments? The next step should be for the staff person to contact their supervisor, the building manager, the director or whomever protocol dictates. In some circumstances, it might require staff to evacuate the building. Fig. 2 is an example of a first responder instruction sheet as used by the University of California Riverside. (For another approach, see CalPreservation’s website.^[25])

Security

When assessing risks it is important to evaluate the current status of security and determine what extra measures are needed both before an emergency and during disaster response and recovery. This is especially true of areas that store high value items.

During the Response and Recovery, the building and collections will need to be secured from unauthorized entry. Volunteers and workers should be screened and proper documentation filed. Media and crowds may need to be controlled. Is there adequate key or access card control?

REPORTING AN EMERGENCY

The following is a list of the 4 calls the person discovering an emergency situation must make. If you are the first person on the scene, determine the nature of the emergency and make the appropriate calls. Ensure your own safety first!

1 st Call:	For FIRE - PEOPLE PROBLEMS-POLICE WATER OR ELECTRICAL Emergency (Day) Evenings/Weekends	
2 nd Call:	Library Administration (Day) Evenings/Weekends	
3 rd Call:	PEOPLE PROBLEMS, Circulation Dept. BUILDING DAMAGE, Facilities Manager (Day) Evenings/Weekends Cell Phone COLLECTION DAMAGE, Preservation Librarian Evenings/Weekends Cell Phone	
4 th Call:	Your Immediate Supervisor (Day) Evenings/Weekends Cell Phone	

Note: In some emergencies you may need to locate a single line phone or use a cell phone to make the necessary calls or send runners. Refer to page_____ in the Disaster Plan for the list of single line phones and their locations.

Fig. 2 Reporting an emergency.

Are there alarms and are they monitored by an entity outside the building? Are there security personnel patrolling, even when the building is closed? Are the items tagged in some way to set off an alarm if taken from the building without authorization? The findings should be analyzed and developed into an action plan and filed in the Disaster Plan.

Floor maps

Almost all facilities, which are open to the public, have the “You Are Here” floor maps. These usually show the main features of the interior of the building such as rooms, stairs, elevators, emergency exits, restrooms, etc.

A disaster response and recovery floor map should have all of this and much more, and because of this should probably not be posted publicly. This “emergency map” should be an accurate representation of storage areas (for example, book storage areas should accurately reflect the number of ranges of book stacks), the location of disaster supplies, and as already mentioned, the priorities of the various collections as well as the location of fire alarms and extinguishers; The maps should also note the location of water cutoff valves to the building and electrical panels. It also makes sense to include projected area for the Command Center and potential sites for the staging areas for triage and pack out.

The detailed floor map prepared in the Preparation phase has many uses when an emergency is discovered. First, it is used to direct fire, police, and custodial personnel to the correct location. (Library of Congress call numbers and other classification systems usually mean nothing to non-library personnel.) Second, these maps are used by staff doing assessment of damage. And third, when damaged areas are correctly marked on an accurate map it is easy to visualize the extent of the affected areas and start planning for response and recovery.

Response Actions

In order to respond efficiently, the Response section of a Disaster Plan contains information and actions needed to respond to an emergency situation in order to lessen the effects, as well as protect property and save lives. It also includes actions necessary to evacuate or retrieve collections and property from damaged areas and “first-aid” measures to stabilize collections.

Useful Tool: “The Detailed Building and Site Assessment,” available on the National Center for Preservation Technology & Training Web site, is a “three-page form that may be used to make a more intensive survey of damaged properties after natural or manmade disasters. The form requires some knowledge of architectural

history and survey techniques in order to produce the most accurate results. It is intended for use by preservation professionals.”^[26]

Damage assessment

Keep in mind that when cultural collections are damaged or at risk of damage, time is of the essence. In fact, the first 48–72 hours, following a disaster are usually considered the most critical for the long-term viability of the collections. Depending upon the size, extent, and type of the disaster, access to the storage environment may not be possible. While the inability to see the condition of the collections can be very stressful, it is vital to refrain from entering the damaged areas until the fire marshal, police, or other official has declared it safe to do so. Regardless of the collections’ value, the safety of staff and patrons safety should never be compromised. As this may be the only “slow” period before the staff is immersed in the recovery process, it makes sense to start preparing. For example, is the area that was planned to become the base of operations for the Command Center still usable? If not, what else is available that has electrical power and access to phones and computers? Call all members of the Command Center Team to meet and start the planning. If safety personnel can estimate the approximate time the area will be accessible, this would be the time to inform staff who are on-site and not part of the Command Center to go home and wait to be called or to report back at a specified time. Contact should also be made with staff not on the premises to alert them as to when they might be needed. Review the Disaster Plan and Salvage Priorities, and assemble in-house disaster supplies.

Once the building or storage area has been declared safe to enter, proceed with caution. Assessors should enter in pairs, rather than alone, wearing protective clothing, footwear, and carry a means of communication such as a cellular phone or walkie-talkie. Document the damage with pictures and/or videos. Take copies of the floor maps to mark the damage to help visualize the scope of the disaster as described in the Floor Map section. Not only will photographic documentation assist in determining treatment needs, but it also fulfills requirements for insurance coverage and FEMA. Remember “even things which seem insignificant now may prove to be very important as you negotiate with insurance adjusters” (SOLINET, “Actions for the first day after”).^[27]

In some situations, only a limited number of persons may be allowed entry into the building or must be escorted by police or fire safety personnel. Whatever the case, the goal of the assessment is to determine the scope of the damage. Where exactly is the damaged area? Is it confined to one particular area? Has it affected the floor below or above? Estimate how many items are damaged and/or threatened. Are there different formats involved? In a disaster, a quick response is critical and valuable time

may have already been lost during the time the building was inaccessible. Time lost may increase the likelihood of a mold outbreak. Therefore, the damage assessment must be as efficient and timely as possible.

Assessors should note additional hazards or areas that need to be stabilized. “It is essential that whatever damage there is to collections be limited at this time.”^[28] If possible, “create an inventory of found items, dislodged architectural features, decorative fragments, furnishings, collections. **DO NOT THROW AWAY MATERIALS AT WILL.** Many items may prove salvageable as the restoration and rehabilitation projects proceed.”^[29] Assessment of the disaster site will yield useful information for determining whether additional, external, assistance is required. It also allows staff to obtain a more realistic sense of what additional supplies may be required and for what purpose. Visual documentations will inform the decisions that are to follow. Other questions for consideration include: whether or not recovery can be done in-house with staff; whether wet materials should be shipped off-site to a commercial freezer or be sent immediately to a vacuum freeze-drying facility or some other process; whether a consultant will be necessary; whether to use a commercial disaster recovery firm; whether to store dry materials out of the building? Keep in mind that even with this preliminary data the salvage plan may need to be revised during the actual salvaging process so it should be as flexible as possible.

Once the damage assessment has been completed, and the area declared safe to work in, the next step should focus on salvaging and/or retrieving those resources fundamental to the mission and operation of the organization. In other words, what collections and other resources are needed, and what steps need to be taken to have the facility operational again? Of course, resources will vary dependent upon the facility, extent of the damage, and availability of responders.

As the immediate threat of a disaster begins to dissipate, the first thought is to begin the salvage process as quickly as possible. While a fast response time is vital be aware that “during this phase, many historic structures and properties are needlessly lost and damaged through hasty clean-up procedures.”^[30] Therefore, the need to proceed with care and caution—and yes, patience—cannot be stressed enough.

Salvage

Starting with the highest level priority that is accessible, carefully transport materials to the staging/triage areas where, while keeping some type of inventory control (with barcodes or numbers, etc), items are sorted by their condition (wet, damp, dry) and packed using the instructions written during the Preparation phase. During a large disaster is not the time to decide whether an individual item needs to be kept or discarded. Those decisions can be made when the items are returned to the building after

drying. Materials with any sign of mold should be isolated from other items as soon as possible.

Recovery Phase

After the damaged and threatened assets have been moved from the building, either to a freezer or drying facility or, if dry, to store in another part of the building or off-site, it is time to prepare the building for their return and reopening to the public. Documentation regarding actions to take after an emergency, in order to rehabilitate the materials, building and storage areas, and return to full operations should be in the Disaster Plan.

Building concerns

Before the materials are returned to the building, several issues must be addressed. First, the facility must be declared ready for occupancy. Did the after-the-disaster building assessment include examining and addressing the building's structure, such as walls and the roof? Are there holes in the physical structure of the facility, for example, which may place the already damaged collections at further risk?

Is the Heating, Ventilation, Air Conditioning (HVAC) system fully operational? Has it been examined by a qualified technician? Have the vents and air ducts been checked for mold and/or soot? Do the filters need replacing? Is the security system operational? Have the facility's fire detection and extinguishing systems been thoroughly examined and reset by the fire department, and determined to be working at full capacity?

The conditions of the storage areas are equally important. Having salvaged, cleaned and stabilized the collections it would be counterproductive to place them in an unclean or unsafe storage environment. Therefore, before relocating the materials "check every shelf, drawer and surrounding floors and areas" to be sure that the requisite cleaning has actually been completed.^[31] If yes, are all surfaces completely dry? If left unchecked, excess moisture in the environment may result in mold growth; therefore, double-checking to make certain that the area is completely dry will save both time and the health of the collections and staff.

Returning collections to the building

If accurate inventory control was maintained during the removal of items from the building then the staff should know the location of each item. This provides an opportunity to return things to the building in a logical manner and reintegrate them into the rest of the collection. If not, the result can be chaos.

If possible, the dried and/or restored items should be unpacked in an isolated area with ample space for the material to be spread out for examination, sorted by

format and later, put into a logical order for return to storage or display. This makes it easier to maintain accurate records of materials and the decisions made about them. This organized, systematic approach allows trained staff and consultants to assess material for specialized conservation treatment, withdrawal, replacement, or repair. What can be repaired in-house? Which need a conservation specialist? Are there items that are damaged beyond repair? Should they be discarded? Another reason for the items to be isolated before reshelving is that an insurance claim settlement cannot be completed until loss-evaluation is completed.

Once the treatment needs are determined, the remaining materials can be returned to permanent shelving/storage. However, even after the materials are returned to their permanent location, spot-checks for mold should continue to be done regularly for at least 6 months.

Debriefing, revision, and more training

Every disaster plan needs to be established according to the needs and demands of the institution that it is meant to serve. In addition, it is very important that the disaster plan cover all types of disasters, big and small, with clear instruction on what needs to be done. The plan must be reviewed frequently so that any necessary changes and updates can be made.

Throughout the disaster, debriefing sessions should be held so as not to lose any information that will help improve future response. The Command Center Team should have a simple list that can help them to make a final assessment of how well (or not) they responded to and dealt with the disaster. How did staff perform? In what areas could they benefit from more training? Were supplies adequate? What about communication and cooperation between departments, divisions, and outside help? Was record keeping accurate? How efficiently were things handled? What were the unexpected problems and their solutions?

CONCLUSION

The topics discussed in this entry deal with some of the most important factors to consider when charting a plan of action for preparing for and responding to threats to our cultural heritage. Even though the hope is that we will never have a need to use the disaster plan, it pays to be prepared. Making sure that information is accurate and current, staff trained, and emergency supplies readily available will place us in a far stronger and more prepared position to respond to a disaster—should it happen!

Every cultural institution needs a Disaster Plan that is subject to continual review and revision. The most effective plans cover every likely contingency and

involve as many of staff as possible in the planning and training phase. A well-informed and well-trained staff can help with every step from planning and preparation to rapid response. A plan written by one or two specialists soon becomes a dusty, forgotten plan; a plan produced and practiced by an entire institution is the strongest defense against incalculable damage and irretrievable loss.

APPENDIX:

RESPONSIBILITIES FOR DISASTER RESPONSE AND RECOVERY

There are many responsibilities that must be assigned to a group or specific staff to make a successful response and recovery. Doing this in the Preparation stage of disaster planning and making sure everyone is clear on their assignments will eliminate lost time. It is recommended that each person have two backup people trained in the performance of the same duties.

Management

- Responsible for overall management of recovery and salvage operation (often a team of upper management personnel called the Command Center)
- Determines the kind of salvage necessary based upon assessment and collection priorities
- Determines when to begin salvage after consulting emergency personnel and Facilities Management
- Determines the type and level of preservation response
- Determines timetable for recovery
- Receives reports and analyzes progress; makes adjustments accordingly
- Designates treatment area(s)
- Decides on restoration of services
- Secures information needed to establish replacement costs for damaged or destroyed

Communications

- Notifies and assembles the members of the Command Center Team
- Notifies with staff workers who have been trained in packing our procedures (often called the Disaster Action Team)

- Receives reports from Team members
- Communicates with the other members of the staff keeping them informed of the status of the recovery progress
- Responsible for public relations with media and is the only person to officially speak for the institution
- Interacts with the organization to which the entity reports
- Works with emergency responders (Fire, Police, custodial staff)
- Tells library staff and volunteers where to report on the advice of the Disaster Response Director
- Contacts Insurance Company or Risk Manager and fills out required forms.

Personnel Issues

- Provides up-to-date information on how to reach staff members
- Deals with union contract issues
- Health, safety, and comfort (physical and emotional) concerns
- Screens volunteers

Assessment and Documentation

- Ensures proper documentation of damage (pictures, video, etc.) to building, furniture, and collections
- Estimates the type and extent of the damage
- Reviews the collections priorities list and confirms or adjusts it based upon the assessment of damage
- Estimates number of personnel needed to complete the work and how long clean up will take
- Evaluates and recommends whether or not recovery can be done in house with staff; will involve shipping material off-site to a commercial freezer of a vacuum freeze drying process; the need to bring in consultant(s); use a commercial disaster recovery firm; storage of dry materials out of the building; decision to store wet materials in a freezer or send immediately for vacuum freezing drying
- Identifies locations for storing materials out of building if a commercial disaster recovery firm is not going to be used
- Formulates logistics for packing out and moving materials out of the building if a commercial disaster recovery firm is not going to be used
- Keeps inventory control of items being removed, discarded, etc.
- Records all major decisions and a chronology of events
- Keep records of materials moved to other sites

Security

- Secures and protect the building's contents

Financial Issues

Figures the monetary impact of all decisions
Arranges for funds necessary to buy supplies, equipment, food, etc.

Salvage Operations

Trains and supervises work teams in proper packing and personal safety
Schedules and deploys work teams
Prepares regular reports on work team progress for the Command Center
Transportation and relocation activities
Arrangements for removing books from site
Arrangements for equipment and supplies
Responsible for handling and treatment of materials from the time they are removed until they are reshelfed

Supplies and Equipment

Contacting outside agencies for services and supplies
Responsible for ordering, delivery, and dispersal of sufficient quantities of the right materials for packing out
Responsible for ordering, delivery, and dispersal of sufficient quantities of food, water, and other comfort items for the workers
Transportation of supplies and materials and the movement of damaged collections

Building Issues

All issues leading up to the eventual restoration of the building to normal
Organizes the orderly return of materials to approved shelving
Identification of locations for response and recovery activities
Supervises in-house cleaning and drying

Recovery Operations

Works with appropriate bibliographers and serves as liaison to cataloging and acquisitions to record destroyed items and to arrange for replacement copies
Prepares report for the Command Center, including photographic record, on the rehabilitation process and unsalvageable materials
Acknowledges and thanks people who have participated in the recovery
Rewrites the disaster plan in light of lessons learned

User Issues

Where can we refer our users until we can open again?

Can we establish some basic services for users in some part of the building or nearby?

Document Information Systems

K. van der Meer

Faculty of Electrical Engineering, Mathematics and Computer Science, Delft University, the Netherlands; Information and Library Science, IOIW, Antwerp University, Belgium; and D-CIS, Delft, The Netherlands

Abstract

From characteristics of information, documents and document information systems (document IS), motives to use document IS are described. A few cases are presented.

The functional aspects of document IS are described, derived from ISO standard 15489 on records management and the Sarbanes–Oxley law, and made operational in MoReq and DoD standard 5015.2. Explicit attention is given to related subjects from a viewpoint of document management: information sharing (workflow, knowledge management), and interoperability of Information and Communication Technology (ICT) tools; authenticity because of the possible evidential value of documents; and digital longevity because of the possible long-time function of archival documents.

The technical aspects answer functional demands; important information science standards, and standard components for 12 characteristics of document IS are described, among others ODMA, the XML family, OAIS, and metadata schemes.

The design methodological aspects answer functional demands and technical possibilities. Models are introduced and the way of working of, e.g., a digitization project is described.

INTRODUCTION

In the past, information was scarce and precious. (Information denotes in this entry an entity from the series data-information-knowledge-wisdom. Information should be recorded, have meaning, and be able to change a person's knowledge: "Information is a body of data on a semantic level.") Information was a matter to be preserved carefully. But today people are drowning in information.^[1] All civilized people are "dataholics." Everyone has to cope with the information overload. And still users are thirstier for information and knowledge than ever; one cannot afford to be ill informed. Information is rated ever higher, "the fourth production factor, the essence of economy, and the fundament of human culture."

Information is a strange commodity. Information can easily be multiplied and spread once it is generated. Information does not vanish when it is being used. Information can be reused and inserted in new documents, without glue, seam, or welding. Information is not an object, but a representation of an existing or intended reality.

Documents contain information. (Due to Information and Communication Technology (ICT), the word document is not used for hardcopies only. A document is defined as "any object which has the purpose, or to which the purpose is given, to serve for the perusal of the data of which it is the carrier." The object may be a book, report, journal article, form, contract, letter, etc.; the data carrier may be paper, CD-ROM disk, microfiche, etc.) The information in documents is ill-structured; its semantics

depends upon a context. Ill-structured information is more difficult to handle for a computer than well-structured data, but it has become feasible. So, there are document information systems (document IS) to keep document information for all those documents that need to be read if necessary, to support our memory, and to serve as witnesses of transactions, and perhaps even to give evidence of today's circumstances in a distant future. The two seemingly conflicting views, information overload and information requirements at the same time, are resolved by document IS to handle, consult, share, draw attention, store, reuse, and discard information—the tasks of librarians, archivists, record managers, document managers, and knowledge managers. (A document IS is defined simply as an information system of which the data is of document nature. The database of a document IS contains references to documents, and it may contain (parts of) documents in the form of texts and/or document images.)

Former ideals of the paperless office have vanished. Paper books, documents, reports, and records have their advantages: they are common, cheap, easy to use, and legally accepted. Electronic documents have other advantages. They can bring savings in the document sector—the economic motive. Without ICT support, control of the mass of electronic documents is impracticable—the manageability motive. Documents have moving pictures and sometimes sounds, or spreadsheets and dynamic links—the presentation motive. Organizations face increasing quality requirements of their products and services, and thus have increased quality needs of document

information and information retrieval facilities—the quality motive. Documents are open to support collaborative authoring, and they can be used everywhere and at all times—the usability motive. These and others motives call for document IS.

If someone still thinks a document IS is a luxury, one may recommend trying to do without. A nasty example of what that means was seen after the destruction of the World Trade Center on September 11, 2001. The memory of many organizations in the Towers had been destroyed. They had to try to reconstruct their organization's transactions and assets when much of the paper was gone, the servers that stored all electronic information were gone, and many employees did not survive either. Resulting ideas on the value of document management have been described by Cox et al.^[2]

This entry starts with a few cases. Then, in the section on the functional requirements for document IS, ISO standard 15489 and the Sarbanes–Oxley law are presented, two firmly established foundations, as well as the resulting software requirements in MoReq and the DoD 5015.2-STD. Explicit attention is given to related subjects from a viewpoint of document management: information sharing (workflow, knowledge management) and interoperability of ICT tools; authenticity because of the possible evidential value of documents; and digital longevity because of the possible long-time function of archival documents. Then, in the section on the technical aspects answering the functional demands, standards, and standard components of document IS are discussed. Examples are the Open Document Management API (ODMA) for information interchange between applications; the eXtensible Markup Language (XML) syntactical data model family; the Reference Model for an Open Archival Information System (OAIS) for preservation of digital information objects that have to be kept for a long-term; metadata schemes for information retrieval; and others. The section on design methodology, as an answer to functional and technical demands, focuses primarily on models of documents, information, users, and usage; and on design questions in, for example, a digitization project.

A FEW CASES

From a few practical cases the highlights are concisely presented.

1. A medium-sized industrial firm wanted to reduce the costs of document information handling (No increase in the number of document managers anymore). The organization wanted to control the design process: each phase of the project needed approval. The functions this firm wanted were common to document management software: they were equivalent to the Model Requirements for the management of

electronic records (MoReq) scheme. The document usage and working time spent on documents were thoroughly investigated. A classification structure was designed. The economic aspects of the document IS were carefully studied. Part of the process was outsourced, for which a request for proposal was written. Business Process Redesign was postponed.

2. A consultancy firm wanted to facilitate reuse of its projects reports by other team members. The needs and wants of the organization were investigated; they were to make reports easily accessible, draw attention to relevant items, ensure security of the report, and guarantee that expertise of consultants is maintained in case of job hopping. It required the prescription of a standard for the reports of the consultants, which took several iterations. The document IS was to be made available in an intranet; it is an internal Web application.

In the design phase, the setup and tools were demonstrated, and in a short course the ICT and the corresponding procedures were discussed. The consultants have been encouraged to share experiences. The document IS was a start to knowledge management, which was indeed one of the purposes of the project.

3. A ministry has an investigation service for environmental frauds. In the research stages, a wide range of information sources is used and produced. The document IS should improve the level of document management support, make the status of each process clear, and guard time limits. The main technical requirements were control of documents, folders, and user's rights; control of descriptors for information retrieval; control of the applications accessing the document repository; compatibility with the software already in use; and document data conversion. This is quite a list, but even more effort was needed to bring around the change of work: the employees had to change profoundly their way of working with documents; the records management unit had to change from routine "information handling" to "organizing document management."
4. A Royal Library, having its own collection but also responsible for preservation of all publications of the country, wanted to renew its information infrastructure. The data structures and software should enable interoperability for services and data from its own collection, its national task for publications and other collections. The infrastructure encompasses XML as an information structure, Web services based on XML and the eXtensible Stylesheet Language (XSL) and the HyperText Transfer protocol (http), facilities for query languages, the use of a standard metadata scheme (Extended Dublin Core), Digital Object Identifiers, and the use of the redirect facility OpenURL.

5. A University wanted to build trusted digital repositories. What technology exists to ensure trust? One answer is: make XML containers, store the original bitstream, zero or more bitstreams in a converted format (!), and the metadata in an XML container, use a digital signature and use a persistent identifier. For harvesting the Open Archives Initiative–Protocol for Metadata Harvesting (OAI–PMH) was used. The use of open standards is stressed. Other organizations, among others a city archive and an institute for historical information, came to the same setup as the University.

In all these cases expertise is needed both from document management, information retrieval, collection management, and knowledge management and from the ICT domain.

The cases differ with respect to the problems, the goals, the project plan, and the type and size of costs and benefits. That is on purpose. There is a wealth of problems in practice. Many cases could be added. Due to their differences, it is no use to write a cookbook. However, functional and technical requirements and design issues can be discerned and best practices and guidelines can be given.

FUNCTIONAL ASPECTS OF DOCUMENT IS

Procedures

Document IS starts by proper document management procedures.

The ISO standard for records management, ISO standard 15489, describes “best practices” for records management. The standard is partly based on the older Australian AS 4390 standard. It states economic and legal reasons for records management, strategies, and operational guidelines for best practices; and actions to be taken: management, responsibilities, education (!), control, ICT infrastructure, records ingest, metadata, access, and security. This influential standard is in a way the best thing that happened to records management for a century.

Another way to draw attention to records management procedures is the U.S. Sarbanes–Oxley Act, in effect since 2002. This Act, often abbreviated as the SOX Act, has a profound impact by its legal character. U.S. businesses legally need to manage, control, and preserve their information. Every company has to control the management and procedures of information and management, the executive control of the records management program, and the technical environment of their records. It is considered to be a crime to delete information with the purpose to obstruct inquiries into proper management.

Of course, ISO standard 15489 and Sarbanes–Oxley did not come out of the blue. They reflect a modern view

on centuries of filing and archival practices and proper business management practices. But currently, ISO standard 15489 and Sarbanes–Oxley are a concrete-based foundation of document IS.

Software

Document management has close relations to other requirements. It makes no sense to file and archive documents if you cannot find them, so retrieval must be supported. It makes no sense to store documents if someone else cannot access them (if that person had the right to access it); this leads to the demand of information sharing, workflow management, knowledge management through groupware, and also the important demand of technical interoperability. For these functions, separate software exists, that may be connected to document management software.

One can distinguish the following types of software applications:

- Document management software, emphasizing document capture, control tools, folder management, version management, and security facilities.
- Information storage and retrieval software, with metadata bases and elaborate ranking.
- Library document management, with retrieval and loan facilities.
- Workflow management, with business process building facilities, document routing, item status facilities, and time control.
- Information sharing and knowledge management packages; groupware.

Records Management Software Functions

The “Model requirements for the management of electronic records” (MoReq) is a “standard” used all over Europe.^[3] In the United States, the U.S. Department of Defense (DoD) 5015.2-STD is used.^[4] The National Archives and Records Administration (NARA) endorsed this DoD standard to all federal agencies. Both MoReq and DoD 5015.2 state the functionality for applications for electronic records management. Records management has a wide scope. All kinds of people create, receive, and retrieve records as part of their daily work, and they need all kind of operations. That work is supported by records managers and archivists and by the records management application. As a consequence of the many types of operations, the functionality is extended.

Operations, demands, and facilities have been prescribed for functions such as process control, security, classified marking and declassification, retention and disposal, retrieval and rendering records, administrative functions such as changing and deleting records, metadata

requirements, and nonfunctional requirements such as performance, system availability, and legislative requirements.

Interoperability

All kinds of organizations face the demand of interoperability. There is a mass-document information exchange between governmental levels; between businesses for reasons of e-commerce; and for common catalogs like Picture Australia.^[5] Picture Australia offers an online portal with search facilities to find digital photos that are not owned by themselves but stored in repositories all over Australia. With a click on a thumbnail you get the whole photo. Picture Australia is an archive without an own collection, all photos reside at the participating organizations. That is an extreme example of interoperability!

The demand on interoperability is a response to the trend to globalization, enabled by ICT. Networked organizations have developed; loosely coupled, seemingly independent organizations without much common authority. Memory organizations like archives, libraries, and museums, and businesses form electronic networked organizations, as well as businesses that collaborate via electronic documents. They share electronic information, exchange information, and reuse each other's information. Interoperability has become an enormous important aspect of document IS.

The participating organizations may be more or less alike, partly colleagues and partly competitors, with horizontal connections, characterized by common or mutual information use. In other cases suppliers and customers of information can be discerned, with vertical connections. The cooperation is based on information exchange. Establishing functional requirements for common document IS for a networked organization consisting of memory institutions (or businesses) without much common authority is difficult for the following reasons:

- There is a problem (for instance, poor service, poor coordination, high costs of the end product, long delivery times of products or services), but the fact that there is a problem does not by itself lead to collaboration.
- The necessary conceptual and empirical model of the new situation at business level is not shaped.
- As a consequence, at employee level it cannot be predicted how the new situation will work out, so that no one can tell senior staff and personnel exactly how their work is going to change. This leads to organizational fuzz.
- It takes time to realize good cooperation with another organization (do not underestimate the *time* needed to realize good cooperation between organizations).
- Insufficient knowledge of ICT issues for common use of document IS.

Authenticity

For document information, three types of values can be distinguished:

- Informational value: the document describes an existing or intended reality.
- Evidential value: the document is a witness of a decision or a transaction.
- Cultural-historical value: the document describes a historical reality.

Most people have for documents only the informational value in mind and realize their evidential, legal value only if they need proof. The evidential value must not be neglected! A document can have evidential value only if it is authentic (if the document is what it purports to be). The content, structure, layout, context, and (if applicable) behavior of the document must be proven to be identical to what it was like in the past.

Authenticity is for an electronic record in a document information system a more difficult item than for a paper record. The fact that a bitstream has to be rendered in order to be readable brings about the questions: what do we mean by authenticity in this case and how to realize authenticity of digital documents.

International Research on Permanent Authentic Records in Electronic Systems (InterPARES) is the major initiative to bring the concept of authenticity applicable to our electronic era.^[6] The InterPARES 1 project resulted, among others, in terms of assessment of authenticity. To assess the authenticity of an electronic record, the InterPARES report states the preserver must be able to establish its *identity*, i.e., the attributes of the record that uniquely characterize it and distinguish it from other records; and demonstrate its *integrity*, i.e., the record is complete, whole, sound and uncorrupted. Next to an overview of the custody—who kept this record and how—this means that the records need a quality check before they are transferred to the document information system where they will be kept, and the records must be maintained after transfer.

Gladney and Bennett studied the authenticity and trustworthiness and genuineness for derivatives for digital objects and transformed text, and also for a broader domain: analog signals, performances, artifacts, and natural entities.^[7] As a result of this work they propose the definition: something is an authentic copy if it is a *sufficiently faithful* derivative with true *provenance*.

Authenticity should be either 1 or 0; a document is either authentic or it is not. The finding of Gladney and Bennett (*sufficiently faithful*) is not at ease with the demand of either 1 or 0.

Hedström and Lampe investigated the result of various forms of preservation (migration and emulation) of Chuckie egg, a game.^[8] The game has been migrated and

emulated and users played the original and a preserved game. As a result, the game is supposed to be authentic if there is no longer a difference in playing the original and the preserved game, although the software is different! So, evidently, for a given user group a *test* can tell the authenticity of a digital object upon change in the ICT infrastructure.

OAIS states that an information object in a document IS will be preserved for a designated community. The designated community must be defined in order to predict what the document should be used for. So, the community and the foreseen use define the measures to keep the document authentic and this defines the test setup to decide whether the document is still authentic in the future.

Next to the demand to describe the designated community, OAIS defines a Preservation Description Metadata scheme with four types of metadata: reference information, context information, provenance information, and fixity information. The reference information is meant to define the identity, the provenance information must provide the demanded true provenance (custody!), and the fixity information must indicate the data integrity. That could function as a solution for the demands that InterPARES disclosed.

Digital Longevity

Due to the urge of ICT innovation, the life time of digital information objects that are represented by bitstreams that have to be rendered, is small. The average maximum life time of a digital information object, a program, or digital document, may be 5 years. In sharp contrast to the short life time of digital objects, an archive demands many of its information objects, digital or no, to have lifetimes that may easily exceed a century.

The changes in ICT within the time of even one generation are such that within a few generations we can foresee a big “Byte out of history” from our times.^[9] Content, structure, lay-out, context, and/or behavior of digital information objects are at risk by the urge of ICT innovations.

In order to preserve electronic records, the refreshing strategy will periodically be necessary: all data on a medium are transferred to fresh media so that the bits are “square and fair” at a new copy of the same type of medium. If the medium is becoming obsolete, the data will be transferred to a more modern type of medium, the strategy of migration. A study of ICT standards, the building blocks of our digital information objects, in time, shows that they are aging fast. The data format and application type get obsolete, too. In that case, the bit stream is “converted” to a more modern standard, data type, or application type (in computer science the term porting is used for this strategy). In cases like this, an audit is necessary to be able to ensure that the result conforms to archival demands.

In the emulation strategy, a new computer system “behaves” like an old one. The Universal Virtual Computer (UVC) emulator, based on a minimal and future-proof computer instruction set, has been developed by Van der Hoeven.^[10] Kol showed, that it takes a computer scientist no more than two hours to express an existing data format to a future-proof instruction set (in UVC terms: a logical data schema) that can be executed in a distant future.^[11] This seems to be a solution to ensure longevity for digital records in the very long run.

TECHNICAL ASPECTS OF DOCUMENT IS: STANDARDS AND STANDARD COMPONENTS

The technical aspects for document IS start from functional requirements of document IS, that have been stated in ISO standard 15489 and Sarbanes–Oxley; to which demands for search and retrieval, sharing information, and possible long-time storage have been added.

The hardware for a document IS is well known from other ICT applications: servers, storage device, monitors, scanning equipment, storage media readers and burners, printers, and telecom. For software, there is a growing number of (information science) standards and standard components for document IS. Some important ones are discussed here.

Storage Media

It has long been recognized that standards for exchangeable data carriers are indispensable. The ISO standard 9660 for CD-Rom and ISO standard 11560 for a common type of Worm disk were the first well known standardized media. From a standardization viewpoint, storage media standardization is a success story. There is a list of some 150 standards for data storage on the Web site for Interchangeable Media for Mass Computer Storage.^[12] They enable ubiquitous media use!

Software Selection

The choice depends on the type of support that is needed, of course. Overviews for package selection containing detailed descriptions help to draw a short-list.

Tailor-made adjustments to software are often needed. Reasons for those demands can be summarized as: we are different, we know better, we cannot wait, and we want to be on our own. These reasons have been put forward for 20 years now. Although additions and adjustments can be useful and necessary, a warning is in place to be careful with them. Every addition carries the burdens of increasing ICT service costs, continuing difficulties to upgrade existing software, and making work procedures more rigid.

ODMA

The ODMA^[13] enables applications to interface seamlessly with a document management client. ODMA offers the support to create, edit, revise, and manage documents. ODMA is very successful, to be judged from the fact that most document management packages are ODMA compliant. ODMA's website^[13] also gives a list of ODMA-compliant packages.

Persistent Identifiers

A persistent identifier is a unique label that is assigned to an information object and that identifies and locates that object forever. By using persistent identifiers, one hopes to avoid dead links (http code 404) and related problems. But it is also avoided that, in order to make electronic documents accessible, someone must maintain the data locations or update the references upon every change. Instead, indirect links to the resources are maintained using a persistent identifier on the one side that is coupled to an updatable reference to the location on the other side. The principle of persistent identifier is based on the redirect principle: the persistent identifier is sent to a resolver that “knows” the address of the demanded document. The Digital Object Identifier (DOI) system is an example of a persistent identifier mechanism. An example of a DOI is the Web address doi:10.1177/0165551504045850. If recognized as a link, in Microsoft Word® or PowerPoint® the cursor is drawn over the identifier, the window shows <http://dx.doi.org/10.1177/0165551504045850>. dx/doi/org indicates a “resolver,” the DOI naming authority [in this case identified by 1177, which knows what Uniform Resource Locator (URL) is indicated by 0165551504045850] returns the useable URL and the result of these actions is that the Web page with the current URL is sent to the requestor.

XML Syntactic Data Model Family

The Office Document Architecture (ODA, ISO standard 8613) was never used much. The Standard Generalized Markup Language (SGML, ISO standard 8879) was more popular from 1990 by publishers and by constructors of complex technical equipment (medical photo cameras, airplane engines). The XML is a data model that is an advanced version of SGML that is commonly used, especially for Web-based document IS. XML itself describes the syntactic data model, the Document Type Definition (DTD) or XML Schema describes the “grammar” of the XML syntactic data model, the Extensible Stylesheet Language (XSL) or rather the XSL Transformations (XSLT) describes the lay-out structure, XPath enables to navigate through XML documents, and XQuery is a query language for XML collections. W3Schools Online Web Tutorials are an introduction into all XML family members.^[14]

OAIS

The Reference Model for an OAIS^[15] is ISO standard 14721. OAIS is used by many digital archives that are meant for long-term preservation of digital information objects. OAIS contains important principles. It gives a high-level overview of the handling of the bitstream and the metadata of the bitstream upon ingest, keeping, and consumer request; and allows the description of a workflow for object handling in the archive. OAIS distinguishes the Submission Information Package (SIP) from the Archival Information Packages (AIP) and the Dissemination Information Package (DIP): the information object submitted to the archive by an author may be repackaged by the archive for keeping purposes and it may be tailored to the user's demands upon request! Moreover, OAIS demands to define a “designated community” for which the information objects are kept, influencing which documents shall be kept, and what should be possible with the document in the future, influencing how it shall be kept and preserved, as a result of the (sometimes anticipated) demands of future “consumers” (users)!

OAI-PMH and OAI-ORE

The OAI-PMH is a protocol to harvest metadata of other institutions.^[16] Especially in the document sector, collaboration is necessary; no one organization can afford to use solely its own documents. So, it may become useful to share repositories. Organizations that are willing to give access to parts of their documents or their collections can implement software to handle OAI-PMH requests. They become data providers. A service provider acts as data publisher having a harvester, an application that handles OAI-PMH requests like “listRecords” to get the metadata, builds a database with metadata of the data providers and offers that to the companies that collaborate or top the general public. The original exemplar of the latter is Picture Australia.^[5] A follow-up standard exists: the Open Archives Initiative-Object Reuse and Exchange (OAI-ORE) standard. OAI-ORE is more ambitious than OAI-PMH; it is meant to describe tools for richer services, even Web 2.0-like services, based on digital objects in distributed repositories.

Metadata

The access structure to document information is another main reason for the use of ICT. On the one hand, the flood of documents leads to ever-increasing demands on sophisticated tools to separate the necessary from the unwanted documents. On the other hand, and not less important, increasing quality requirements of the company lead to increasing needs for information retrieval. We refer to situations like “We have had a similar situation before, how did we react to it?” In the past, if the pertinent

documents could not be found quickly they were not searched for at all. Such a question would be answered from memory, and not always precisely. The enhanced quality that is required nowadays by every business and government body is precisely the reason that these questions have to be answered correctly from the relevant documents.

It may be necessary to find the pertinent documents, but the possibilities of finding a document needle in the information universe haystack are poor. Reuse of information objects is furthered by the intrinsic interoperability in standard metadata sets. The following standard metadata tag libraries are often used.

- a. Dublin Core, “DC”, ISO standard 15836, is the best known metadata element set.^[17] It consists of 15 elements. The Qualified Dublin Core, DCQ, adds to DC the possibility to use refinement to the metadata elements, encoding schemes, and extra metadata fields from a small expansion list. Dublin Core is a common tool in digital libraries.
- b. The General International Standard Archival Description [ISAD(G)] was developed in the archival world.^[18] It contains 26 fields, of which reference, title, archive creator, date, size, and level of description (record, record group, collection, etc.) are obligatory. Next to it is the International Standard Archival Authority Record for Corporate Bodies, persons, and Families [ISAAR (CPF)], describing persons and organizations.
- c. The Encoded Archival Description (EAD) is the successor of ISAD(G) for electronic collections.^[19] Like Dublin Core, it has the form of an XML tag library. An EAD record consists of three parts: <eadheader> describes the archival description or finding aid, <frontmatter> describes information that could have been stated on a title page of the electronic record, and <archdesc> contains the archival description itself.
- d. Metadata for records, ISO standard 23081, is a metadata scheme for “document management” records. As of mid-2007 only part 1, principles, has been published; the other parts, more explanatory and providing practical guidelines, will follow. The standard prescribes metadata on the description and the accessibility of records, about the business rules and the business processes, and metadata about records management processes. This metadata element set indeed corresponds to ISO standard 15489 for records management. It is likely to become important.
- e. OAIS describes electronic information packages. The information packages have metadata for packaging information: content information about the content information object, i.e., bitstream, as well as the associated representation information needed to make the bitstream understandable; as well as Preservation Description Information (PDI). The PDI encompasses: reference, the identifier of the bitstream; provenance,

the source of the bitstream, who had custody, and its history; context, stating for instance how this bitstream relates to other ones (e.g., “reply”); and the fixity, that makes alteration in the bitstream perceivable. The OAIS metadata add well to the original Dublin Core.

- f. PREservation Metadata: Implementation Strategies (PREMIS) is meant for digital objects. The PREMIS data dictionary^[20] contains the information a repository uses to support the preservation process of the digital objects. The viability, renderability, understandability, authenticity, and identity of digital objects must be protected on preservation; also digital provenance and relations between digital objects should be preserved. PREMIS builds upon OAIS and uses XML Schema.

Content Representation

Both classification and thesauri are used in the content representation section of the metadata sections. For thesauri, ISO standard 2788 has been developed; ISO standard 5964 was meant for multilingual thesauri. Collaboration between organizations led to the demand for semantics on information exchange. In order to enable interoperability on the World Wide Web, a computer must be able to identify exactly the subject. As ever more document IS are being Web-accessible, this development is important for document IS as well. Ontologies are being developed and implemented. In an ontology the Resource Definition Framework (RDF) is a tool to define a lemma; RDF Schema [RDF(S)] to define relations between lemmas; and the Ontology Interference Language (OIL) and the Web Ontology Language (OWL) are the richest tools to define an ontology. RDF, RDFS, OIL, and OWL are W3C (World Wide Web Community) standards and XML-based.

Checksums

For data integrity a checksum can be used. Entlich describes how checksums are used to determine whether the bitstream in a document IS is still identical to the original bitstream.^[21] A well-known checksums algorithm for this purpose is the Message Digest Algorithm 5 (MD-5). The Secure Hash Algorithm 1 (SHA-1) is more extended than MD-5, SHA-1 may be more common in the future. In order to be able to prove the document has not been changed, in the fixity metadata field of an OAIS-AIP (document), the type of algorithm and the checksum value must be stored, preferably with date and time when it was computed. This is part of the proof of authenticity.

Query Language

Many libraries have used the Z39.50 query language protocol for information retrieval in distributed environments.^[22,23] It enables the client to request that the server

searches databases for information that meets specified criteria, and to retrieve some or all of the identified information. It is meant to control the search session as well. Z39.50 is also known as ISO standard 23950. The Z39.50 standard has port number 210; and the world is adopting the http protocol, port 80, for this purpose. Search/Retrieve via URL and Search/Retrieve via Web Service (SRU/SRW) is a port 80 protocol with Z39.50 semantics. The W3C defined XQuery for the query language for XML repositories.

Data Formats

Adobe Portable Document Format (PDF) must be regarded as the factual standard; PDF/A is a part of PDF for stills, without encryption, private fonts, and patented compression, that is an ISO standard (ISO standard 19005) and suitable for long-time storage (probably much longer than 10 years). The HyperText Markup Language (HTML, ISO standard 15445) is a presentation structure compliant to XML to represent XML in a browser. HTML (and XML documents that are transformed to HTML) and PDF are different types of solutions to the way a bitstream can be presented in a browser. Kasdorf compares PDF and XML; they are complementary and can both be necessary.^[24]

The Tagged Image File Format (TIFF, ISO standards 12234 and 12639), and JPEG 2000 (cf. the Joint Photographers Expert Group; ISO standard 15444) are two more examples of frequently used format standards for visual materials with good prospects to longevity.

The list of information science standards and standard components for document IS could be expanded with items that are not yet common and stable. It can be foreseen that this list will gradually, slowly, be expanded with items that are stable and have been accepted worldwide. There are also ICT standards from outside the document area. They are outside the scope of this entry.

Awareness of standards and standard components is something different from using them without second thoughts. Their use takes time and costs effort. In every case, it is recommended to study whether the advantages to use them match the drawbacks.

Finally, we draw attention to the fact that such an authoritative list of commonly-used standards and standard components could not have been drawn a decade ago. Evidently, document IS have come of age and it is not only necessary, but now also possible to draw up such a list.

DESIGN METHODOLOGICAL ASPECTS OF DOCUMENT IS

The design of an information system for document information requires building upon the functional requirements and technical tools and craftsmanship.

The design means finding a balance between specific needs and wants and profits of an organization on the one hand and ICT possibilities on the other. This balance is important. Too little attention to organizational requirements will generally result in systems that have limited value to the problem-owner; too little attention to ICT may lead to unrealistic and expensive demands on technology. IS design surely is an engineering process!^[25,26]

The benefit is difficult to predict. We found for evaluation of the benefits of document IS, that an ex ante representation of the benefits is rarely fully correct, even if the costs and benefits have been properly calculated. Often, during the design and implementation of the document IS or immediately afterwards, personnel came up with ideas for modification, new developments, task restructuring, or new services. Of course, the original goal was adapted. So, the benefits are partly ascribed to other circumstances. But for measurements on the benefits, then, it is not clear *what* to measure.

Moreover, the increased use of ICT is a step in the development path of an organization. The ability to grow and to change with help of ICT is a vital condition for an organization. (Less kind but more succinctly: an expanding document IS is only a battle in a war.) The problem with benefit measurements, then, is *when* to measure.

There are different types of users. "A good document information system" contains aspects of economic and managerial nature on the one hand and quality and usability aspects on the other hand. Not surprisingly, the aspects of an economic and managerial nature are of more interest to the executive staff, the management level of an organization. The quality and usability aspects refer to the personnel who will be using the document IS every day, the employee level. Important at the employee level is that users will be happy to work with the document IS if it is functioning well. Most employees in an organization will be proud to perform good quality work, and the challenge for the information system designer is to enable them to do so.

For the design of any IS, other than a very simple one, a design methodology is used. (A methodology is defined as a coherent collection of methods and techniques to solve a class of practical problems.) There are advantages to use a design methodology.

Firstly, the experiences of expert designers are used, one can use tested and proven ways to describe an organization (top-down, bottom-up, processes, actors); there are checklists; there is less chance that vital parts of significant organizational and technical problems or solutions are overlooked. Secondly, communication is enabled, there are rules to make representations, documentation and software can be shown in a standardized way to the customers, to problem-owners, and to other members of the design team; communication enables to share work among colleagues.

The use of a design methodology has disadvantages as well. Methodologies are made for problem solving in general, for a class of practical problems. But in practice each design problem is different. Whatever methodology is chosen, it will miss views and tools on some of the problems; some actions will be described too globally and other actions receive needlessly much attention. A methodology will not do the work! A methodology is just a toolbox in the hands of a designer, who does need an open eye for actual circumstances.

The design methodologies differ considerably. The elements of one design methodology may even have no counterpart in another methodology. This leads to the question what kind of elements exist and what elements should be provided to ensure that a document IS can be effectively designed. The Delft framework is used to adjust theoretical views to practical needs. It characterizes design methodologies by the following ways.

- Way of thinking (the “Weltanschauung”—the perspective on the problem domain—from which among others can be derived what objects are pertinent).
- Way of modeling (what conceptual models are made and what are their mutual relations).
- Way of working (what steps and actions must be taken by the designer).
- Way of control (what successive stages are distinguished in the progress of the design and what happens after each stage).
- Way of support (what electronic diagram and scheme tools will be used for the models, the way of working and the way of control). The way of support is the least interesting one. All kinds of tools are available to support representations of static models that are used for document IS. For dynamic situations (like process models and document routing), excellent results have been reported with simulation and animation techniques for dynamic modeling. They need not be discussed here.

These ways may eventually be added to any methodology that is used by or known to the organization for which the document IS is meant.

Way of Thinking

The objects that are pertinent for the document IS are documents, information, users, and usage. These four terms will appear in a document that describes its purpose or for instance from the result of a Balanced Scorecard approach. They then must be the main objects in the methodology and in the actual design. Other terms that can be found occasionally here are: time to complete, action sequence, and queuing. In these cases, document routing and workflow management play a role.

Way of Modeling

A model is a representation by reduction of an all-too-rich and heterogeneous reality (an existing or an intended reality) to something that can easier be understood. Modeling is thus “the science and art of leaving out.” Top management, department managers, employees, ICT management, and others all have their own views on their own relevant parts of reality. Therefore, the relations between models are as important as the models themselves. The way of modeling is a part of the core of expertise of the designer.

Models of document IS will refer to the documents, the information, the users, and the usage.

- Examples of document models: document types, readiness level (under construction, ready, published), and classification level.
- Examples of information models: its (analytical) components: content, structure, lay-out, context, and behavior (for dynamic information); and information quality: correctness, preciseness, timeliness, completeness, and controllability of the information; next to that information relevance to a topic should be modeled.
- Examples of user models: role-based user models, indicating which users have access to the IS; expertise models, distinguishing novice users from experts; and personalization models, for instance the habit to adapt the lay-out of information if it was shown to that user before.
- Example of usage models: processes to which the document belong, document management leads to requirements on, for instance, version management of documents, folder management, appraisal procedures, removal of documents that are no longer needed, selection of documents for transfer to the static archives. Frequency of document use is another example.

In the design phase the attention is usually directed to the new situation, however, one needs a valid and easy but sufficiently detailed description (a model) of the current situation. This is necessary for a proper problem-solving cycle that exists of conceptualization, validation, and verification of a problem situation. Only after the current situation has been described, one or more models of new situations with consequences and benefits can be compared to the current situation.

Modeling is difficult. It takes students a lot of time to learn to model sensibly. A problem and one or more solutions, new situations have to be modeled. The current and new, foreseen situation must be conceptually modeled and represented. It is difficult to make one’s new view explicit, to make choices, to think through a new situation.

Way of Working

The way of working indicates the steps and actions that have to be taken to solve the ill-structured problem of the

design of a document IS. This is part of the core of the expertise of the designer.

1. In order to get an impression of the sizes and amounts the document IS will contain, an inventory must be made up of the document data.
 - a. Data on the static document database (numbers, sizes, requirements on document colors, document storage space, index storage space).
 - b. Data on the dynamic requirements (numbers of incoming documents per day, period of record keeping, printing capacities).
 - c. The technical infrastructure (server requirements, work stations, printers, other peripherals, network requirements for data communication).
 - d. The index structures.
2. Man-machine interaction aspects form an important part of usability. Surprisingly, this aspect still does not always get the necessary attention. The usability of document IS is often not satisfactory. The meaning of document data depends on the context and structure, which is only partly visible on a computer screen with its limited size.

The dialogues should contain command shortcuts and adaptive responses for experienced users, informative feedback during an operation (for instance “please wait”), closed dialogues, and simple error messages.

3. Communication to users and training of users. Users differ in their level of education, their familiarity with computers, and in the frequency they will use the document IS, but they are the ones that decide on its success. This also holds true if the users are the general public. In one case announcements of the automation project were given, a formal introduction, informal demonstrations, and tests with users to find out whether the system is foolproof. Communicative talents of the designer are extremely valuable.

More formally, three consecutive stages are distinguished.

- a. Communication before the document IS will be built (give an introductory course, ask users who will want to participate some time in the design stages).
- b. Communication during the design and development (manage participation, present reports on the progress, show a prototype, let users work with an experimental IS).
- c. Communication afterwards (training, courseware, help desk).
4. Digitization

Papers arrive in the mailroom. Here, it is decided by selection which documents will be put into machine-readable form. The images are put on temporary magnetic media until they are indexed and it is decided for how long they will be kept; then they are put on permanent media. The end users index incoming documents but, even so, information management (the

responsibility for the documents and the index terms) remains centralized. Digitization of documents is costly.

The following design questions are characteristic for a digitization project:

- a. Which documents to convert: digitization of all documents may be costly; but that part that is not digitized loses part of its value, even if it is indicated that there are folders and collections present that have not been digitized.
- b. The quality of the metadata (indexes): if they have to be modernized, corrected, or adapted to the ideas of some cooperative body, they will be very expensive.
- c. The resolution of the images: it seems attractive to make high-resolution scans, but the scan of an A4 page at 300 dpi (dots per inch) results in some 8.7 million pixels (picture elements), the scan of an A4 page at 1600 dpi will need far more, some 250 million pixels. Storage space is cheap but not for free.
- d. Compression of the images: lossless compression is attractive, as original details can always be restored, but lossy compression is stronger. LZW, ZIP, and JPEG2000 can be used in a lossless way. Present and future compression algorithms may bring about that a dead (flipped) pixel results in a dead image, a feature that may be chosen to be avoided.
- e. The color in the images: color schemes that are used most are RGB (Red, Green, Blue); CMYK (Cyan, Magenta, Yellow, and Black); and HSL (Hue, Saturation, Lightness). The standard technology of RGB will result in 24 bits to represent one pixel, each color is represented by 8 bits or 256 possible “color intensities” for that pixel.
- f. The format of the images: next to PDF, TIFF, JPEG 2000, and sometimes HTML other formats are met: BMP, GIF, JPEG, PNG, and others.
- g. Image correction is technically easy; improve contrast, color correction, despecle by removal of surface pollution.
5. The aspect of digital document longevity, digital archiving and preservation is important. There is no experience with the behavior of electronic document repositories over the ages. Important standards are referred to in the section of Technical aspects.
6. For management purposes it must be possible to obtain static and dynamic data from the document IS. Document use and process control to have a managerial dimension. The need to generate management information, however, is not limited to *document* IS.
7. A complex document IS is expensive to design and expensive to maintain. Therefore, possibilities to reduce complexity must always be kept in mind. An example to reach this is downsizing, and if necessary data interchange between modules. Guarding clear

responsibilities of personnel is one more principle. Reduction of complexity is not a problem to *document* IS design only. We refer to standard works on IS design.

8. Both in the design and in the deployment of document IS, tasks can be outsourced. The advantages of outsourcing are the availability of manpower, expertise, and infrastructure. Outsourcing, however, does not mean that the stakeholder gets rid of all responsibilities. An outsourcing situation or a quotation request for outsourcing demands clear statements of the problem-owner on the purpose of the services, the way of collaboration of the partners, the technical situation (hardware, software, functionality, availability, support), the management, the costs, and the legal aspects; the number of legal suits has spectacularly grown. There is much experience on outsourcing document IS, but also on other IS. It is an important issue for which we refer to standard works on outsourcing.
9. For implementation there is a choice between a phased, controlled growth path, and a big bang approach, in which a complete information system is put into use at once. A strong argument for a controlled growth path is the limited predictability of a new system. One should always be prepared for unprepared setbacks. A strong argument for a big bang approach is of economic nature, the big bang approach will bring benefits soon after the complete document IS has been installed, while in a controlled growth path the benefits will evolve only gradually. In practice document IS tend to be complex. That may be the reason that most organizations choose for a gradual growth path.

Way of Control

The way of control indicates how the design process should be managed and controlled. Overall, this is an important issue. A change in document information provision affects an organization so pervasively that organizational understanding and rethinking are vital. Information is a primary production factor, after all. Organizational aspects are a main feature rather than of secondary importance.

1. User acceptance is too weak an approach for the design of document IS. On the design of a document IS user participation or user centered design should be required rather than mere user acceptance. There is a group of design methodologies based on Rapid Application Design (RAD). They adhere to the principle of participation. In fact, the document sector has been aware for a long time of the need to let users participate and contribute to the design and realization process. Mumford's design methodology ETHICS, a thoroughly participative methodology, published

already around 1980, was based on experiences in the document sector.

The flow of phases in projects in this area is something like Joint Requirements Planning—Architecture definition—One prototype (specify functions and construct)—One more prototype—Just one more prototype—Integration of the software with other present software—Cutover (i.e., deployment).

2. Cascade control models flow such as: requirement engineering—global functional design—technical design—programming—testing—implementation. This approach is used if a document IS must fit in a rigid architecture.
3. Extreme Programming, XP, is meant to investigate the ICT possibilities for a domain. The XP way of control is not used too often.
4. In most cases, standard tested and proven document IS applications can be bought and tailored. In automation of document information, software engineering and the quality of the software is important but not the main concern in the realization. There are other points demanding much attention.

CONCLUSION

Document IS are used for reasons of economy, manageability, presentation, quality and usability. This entry contains an overview of functional, technical, and design methodological aspects on document IS.

The functional aspects of document IS derive from ISO standard 15489, with best practices and guidelines for good document management, and the U.S. Sarbanes-Oxley Act, stating legal demands on document management that are impracticable without document IS. They are answered in the descriptions of functions for software for records management that have been established in MoReq and in the DoD 5015.2-STD. There is an increasing demand to find information while an increasing amount is sent every day; there is an increasing demand to share information; there is awareness that in some future a small part of the documents of today may still be used. So, these functions are demanded of document IS, too.

The nature of document use calls for the document being unchanged over time. So, the demands and possibilities to ensure authenticity of electronic documents have been discussed. The UVC approach, based on a minimal and future-proof instruction set, seems to guarantee digital longevity of document information that is represented by a bitstream.

Technical aspects refer to building blocks like standards and standard components for document IS. Some 12 of them are stable and used worldwide. We draw attention to the fact that such a list of standards and standard

components, as described in this entry, can be written down; this is a witness that the field of document IS has come of age.

Design methodological aspects are building upon functional demands and technical possibilities. Most interesting here are models. A model, a representation by reduction of an all-too-rich and heterogeneous reality (an existing or an intended reality) to something that can easier be understood, is in the case of a document IS made for documents, for information, for users, and/or for usage. Examples of models are given. Moreover, the steps and actions to be taken to realize a document IS are indicated, for instance in case of a digitization project.

Document IS being of age does not imply there will be no developments anymore. The increasing value of information is one reason for future changes in document IS; the demand to standardize technical components to use them as standard building blocks or as Web services in applications is a second one; developments in semantics, so that computers will "understand" the information they handle is a third reason for future changes. The author does not contradict the opinion that the development in semantics is a bit further away.

Document Theory

Niels Windfeld Lund

Institute of Culture and Literature, UiT The Arctic University of Norway, Tromsø, Norway

Abstract

This entry provides an overview about the historical development of theoretical reflections on documents and formulation of document theories. Starting out with its Latin predecessor *documentum* and the use of the conception in the European state bureaucracy from the seventeenth century, the first interest for document theory was a professional one and can be observed at the beginning of the twentieth century, closely connected with names like Paul Otlet and Suzanne Briet. While the notion of document and documentation was well established around 1930, it was replaced by the notion of information after World War II, at least in the Anglophone community. Nevertheless, at the same time, a new kind of document theory was emerging, a critical one connected to names like Michel Foucault, Harold Garfinkel, and Dorothy E. Smith. While the “professional” document theory developed by Otlet and others was focused on the knowledge more or less inherent in the documents and to make documents *about* something, then the general document theory developed by critical social scientists such as Foucault is much more about what the documents *are* and *do*. Since the 1990s, there has been a growing interest in general in the notion of document and documentation as well as inside Library and Information Science (LIS). Together with a growing interest in digital documents, document theorists around the world are emphasizing the complexity in document theory and a need of a complementary approach to document theory connecting physical, social, and cultural dimensions in how documents are and do.

INTRODUCTION

An interest in a document approach within the Library and Information Science (LIS) has varied from time to time. Since the late 1980s, there seems to have been an increased emphasis on a document perspective in LIS as well as in society in general. The reasons may be very diverse, depending on the different contexts for using the notion of document.

If one begins tracing the use of the word *document* through history and making a kind of conceptual archeology, one will realize that *document* has been understood in many different ways throughout history. The word *document* and its Latin predecessor, *documentum*, was from its beginnings in antiquity not only something to be held in hand or a piece of written evidence. It was primarily related to teaching and instruction. In 1214, the Latin form *documentum* was registered as meaning example, model, lecture, teaching, and demonstration. The word *document* until the seventeenth century meant *primarily* “ce qui sert à instruire, enseignement, leçon” (something serving the act of instruction, teaching, and giving a lecture).^[1] An oral lecture or instruction could be a document and may indeed have been the norm and prototype of a document. This oral document tradition oriented toward educational purposes is almost forgotten today, and many would think of the legal conception of the document as being its original one dating back to antiquity. However, this conception is more related

to the emergence of the European state bureaucracy from the seventeenth century and onward. In France, it was first found in 1690 in the combination of “titres et documents.”^[1] It is defined as “écrit servant de preuve ou de renseignement”^[1] or “something written, inscribed, etc. which furnishes evidence or information upon any subject, as a manuscript, title-deed, tombstone, coin, picture, etc.”^[2] From the beginning of European modernity and enlightenment, a document is first and foremost a written object stating and proving transactions, agreements, and decisions made by citizens. It was an essential part of the creation of a public bureaucracy across and independent of local customs based on a “droit coutumier” contrary to “droit écrit,” laws and rules varying from place to place, being oral or gestural like handshaking agreements on a market place. Second, documents became a matter of proof, a question of whether the statements in the documents were true or not; the authenticity of the documents became crucial. Many court trials have been and are still dealing with exactly this issue. Third, the document is still an issue of “renseignement,” of delivering information partly drawing on the earlier educational concept of document. It is a piece of writing which tells you something. These three characteristics can be merged into one central phenomenon in the modern society: written, true knowledge. During the eighteenth century, an essential part of the development of modern bourgeois society and especially its public sphere was that the legitimacy of politics,

economy, the court, and science became increasingly dependent on one's ability to document one's rights and claims.

Following the legal tradition, in the late eighteenth century science began to be a question of empirical proof and thus “appuyer (une thèse) par des documents (1876).”^[1] During the nineteenth century, the noun *documentation*, created from the verb *to document*, became a key word in administration as well as in science. From now on, the quality of scientific work depended on the documentation that the researcher could present to his colleagues and the public. It was no longer enough to make a good narrative or to present good logical arguments without empirical evidence. Scientists as well as humanists, especially historians, from then on had to demonstrate true positive knowledge by either making controlled experiments or collecting documents which demonstrated that they had empirical proof as basis for their arguments. This created the perfect setting for the first explicit document theory to be articulated as part of what has been called the first documentation movement, first and foremost led by the Belgian lawyer Paul Otlet (1868–1944).

PROFESSIONAL INTEREST FOR DOCUMENT THEORY

About 100 years ago, around 1900, many European scholars worked together in creating environments and tools for international collaboration among scholars. Many scientific associations as well as international journals were founded. This created also an urgent need for tools by which to find work by colleagues, to locate the publications, and to use the collections of data, collected by scholars. This was the background for the work started by Henri La Fontaine, who within the Society for Social and Political Studies created the bibliographic section of the Society. Together with his younger colleague, Paul Otlet, in 1893, he opened the International Office of Sociological Bibliography. Very soon, in 1895, this was extended to be the International Institute of Bibliography (IIB), being the center for international cooperation able to create its catalog, *Repertoire Bibliographique Universel* (RBU), organized by an elaborated version of Dewey classification scheme resulting in the Universal decimal classification (UDC). All this was being done for practical reasons, in order to provide useful tools for scholars. Neither Otlet nor Fontaine were theoretical people. For Otlet, the main purpose was the organization of documentation on an increasingly comprehensive basis in an increasingly practical way in order to achieve for the intellectual worker the ideal of a “machine for exploring time and space.”^[3]

But in order to realize his ideal and improve the practical organization of documentation, he had to define what is meant by document. For that purpose, he needed a new science of bibliography:

The Science of Bibliography can be defined as that science whose object of study is all questions common to different kinds of documents: production, physical manufacture, distribution, inventory, statistics, preservation, and use of bibliographic documents; that is to say, everything which deals with editing, printing, publishing, book-selling, bibliography, and library economy. The scope of this science extends to all written or illustrated documents which are similar in nature to books: printed or manuscript literary works, books, brochures, journal articles, news reports, published or manuscript archives, maps, plans, charts, schemas, ideograms, diagrams, original or reproductions of drawings, and photographs of real objects.^[3]

Otlet developed a very broad concept of document while he also kept a bias toward printed texts, toward books. He always talked about “books and documents” as well as “bibliography and documentation.” He developed a document theory for libraries, not for social life in general. While the spoken word is the primary focus for linguists, it is the written sources which are of interest for Otlet and his fellows in IIB:

Today Documentation is understood to mean bringing into use all of the written or graphic sources of our knowledge as embodied in documents of every kind, though chiefly printed texts. [...] Knowledge and impressions would last for only a limited time without the help of graphic documents to capture and hold them fast because *memory* alone is insufficient for recollection.^[4]

Even if Otlet acknowledged oral communication as having some value, for him it is graphic documentation that ensures the memory of humanity. Otlet was also realistic about the inevitable diversity of documents:

Individual publications will continue to appear quite independently of each other. They will retain their characteristics of being separate, idiosyncratic, and poorly related to the whole body of knowledge itself.^[5]

But he was very optimistic about the possibilities for and advantages of a *Universal Book*. He strongly emphasized the technical possibilities of new media at the time for realizing the Universal Book as one large *hyper-book*. This book should be created by the so-called monographic principle. It was a question of isolating each *fact* by pulling apart all documents and make a card or sheet for each *fact* by cutting out the original documents and pasting the isolated fact-card into an order, creating a coherent cosmos out of the chaos of idiosyncratic documents. While this method of *codification* could be fatal in an analog environment, destroying the original document for ever, Otlet envisioned the possibilities for a digital *hyper-book*, in which you can cut and paste without destroying the original document. Otlet thought a great deal about how to solve this problem and was inspired by H.G. Wells' ideas about a World Brain.

Even if Otlet primarily was interested in the written documents, he was in principle open for other kinds of documents: not only images and sound recordings, but also natural objects, models, games, etc.^[6] In this way, he went beyond the graphic universe and the library model to the idea of Palais Mondial or Mundaneum as a kind of complete worldwide documentation including all kinds of documents, transgressing the traditions of libraries, archives, and museums.

While there were others besides Otlet who considered the theoretical issues regarding documents, like Walter Schürmeyer and Donker Duyvis, the most important person regarding theoretical discussions on documents is without any doubt Suzanne Briet (1894–1989), the French documentalist and author of many articles on documentation.

Like Otlet, Briet was also mostly engaged in practical documentation and not theoretical questions. At the same time, she was very conscious about what she was trying to accomplish. In order to promote her vision of a new professional field, she wrote a small pamphlet, a manifesto, in 1951, on the basic question: “Qu’est-ce que la documentation?” (What is documentation?), naturally including the question of what constitutes a document. She starts referring to a very general definition: “A document is a proof in support of a fact,”^[7] and to the “official” definition of the French Union of Documentation Organizations from 1935, “all bases of materially fixed knowledge, and capable of being used for consultation, study and proof.”^[8]

At the same time, Briet acknowledges that there may be some theoretical problems related to this pragmatic kind of definition of a document, saying:

This definition has often been countered by linguists and philosophers, who are, as they should be, infatuated with minutia and logic. Thanks to their analysis of the content of this idea, one can propose here a definition, which may be, at the present time, the most accurate, but is also the most abstract, and thus, the least accessible.^[8]

Unfortunately, Briet did not specify her sources and references in this discussion and analysis, but we may be able to identify some of the sources by reading her following proposal of definition:

any concrete or symbolic indexical sign [*indice*], preserved or recorded toward the ends of representing, of reconstituting, or of proving a physical or intellectual phenomenon.^[8]

It appears to be in accordance with the semiotics of Charles S. Peirce (1839–1914) and the theory of three basic kinds of signs: iconic, indexical, and symbolic signs.

From this, one may see why Briet claims that documents primarily are indexical signs compared to the quality of symbolic signs.

This is illustrated in her following paragraph:

Is a star a document? Is a pebble rolled by a torrent a document? Is a living animal a document? No. But the photographs and the catalogs of stars, the stones in a museum of mineralogy, and the animals that are cataloged and shown in a zoo are documents.^[8]

The major difference between the two kinds of objects is that the star and other objects named are concrete objects unconnected with any specific sign, while the photograph, catalog, etc. are specifically intended to represent something like stars, a special kind of mineral, or a special animal specimen such as a new kind of antelope, which Briet uses as an example of the relationship between document and the whole process of documentation. They are initial documents distinguished from what she calls secondary documents. She describes how new documents are created as derivatives or secondary documents, from the antelope considered as the initial document and being the basis for a whole complex of documents like catalogs, sound recordings, monographs about antelopes, articles for encyclopedia about antelopes, and so on, all together creating a new kind of culture for scientists, centers of documentation conducted by documentalists “performing the craft of documentation,” using a new cultural technique of documentation:

The proper job of documentation agencies is to produce secondary documents, derived from those initial documents that these agencies do not ordinarily create, but which they sometimes preserve. [...] We are now at the heart of the documentalists’ profession. These secondary documents are called translations, analyses, documentary bulletins, files, catalogs, bibliographies, dossiers, photographs, microfilms, selections, documentary summaries, encyclopedias, and finding aids.^[9]

Like Otlet, the document theory presented by Briet is a very specific theory on documents with the aim of promoting a new professional field defining the role of libraries as centers of documentation in a very proactive sense.

Both Otlet and Briet played a key role in the international community of documentation, and it was indeed international. It was the foundation for a movement across the continents making it possible to talk about “fifty years of documentation,” as Samuel Bradford did in 1948 working within the international organization of International Federation for Information and Documentation (FID). In 1924, The Association of Special Libraries and Information Bureaux (ASLIB) was created and they founded the *Journal of Documentation* (which is still running). In 1931, L’UFOD, Union française des organismes de documentation, was founded. In 1937, the American Documentation Institute came into existence with a journal, *American Documentation*, and a similar French comité of documentation was created. International cooperation has continued since then, but an important difference between the Anglo-American and francophone worlds began slowly, but

steadily to emerge due to two distinctive traditions for libraries in North America and continental Europe.

While the North American library tradition is focused on the user of the library trying to provide all relevant materials in the most convenient way for the user, the continental European, not least the French library tradition is much more a matter of preserving and taking care of the materials in the library, the documents, and keeping them in a secure distance from the user inside the walls of the libraries.^[10] In a paradoxical way, this difference may explain some part of the decision of the American Documentation Institute in 1968 to change its name into American Society for Information Science.^[11]

GENERAL SCIENTIFIC INTEREST FOR DOCUMENT THEORY

In the late 1960s and 1970s, professional document theory lost power, especially in the Anglophone world, in favor of information theory as the basis for the transformation of the sciences of documentation into information science. However at the same time, a new kind of document theory was emerging, a critical document theory. It was developed primarily within the critical and Marxist traditions of philosophy, sociology, and anthropology.

The French philosopher Michel Foucault states the following about documents in the introduction to the *Archeology of Knowledge*:

[...] ever since a discipline such as history has existed, documents have been used, questioned, and have given rise to questions; scholars have asked not only what these documents meant, but also whether they were telling the truth, [...] all this critical concern, pointed to one and the same end: the reconstitution, on the basis of what the documents say, and sometimes merely hint at, [...] the document was always treated as the language of a voice since reduced to silence, its fragile, but possibly decipherable trace.^[12]

From this case of the discipline of history, Foucault develops a general document theory turning the focus away from the assumed content or message of the document to the very material and active role of documents as bricks or parts in the construction of a historical totality. In his later book on the emergence of the prison, *Discipline and Punish: The Birth of the Prison*, he demonstrates how this document theory not only can be used in historical studies, but also as a critical analytical tool in relation to the modern society in general. This is a fundamental critique of the belief that a document contains a message in itself, as if a book is a document per se. It is only when a particular material thing such as a printed book becomes a part of a constructed totality, such as the literary world, that it becomes a document. When one compares this conception of document to the concept of a documentary

culture by Briet, there actually seems not to be a big difference between Foucault and Briet. However, one may argue that Foucault's critique of the assumption of an inherent content in documents challenges the belief of Otlet of the possibility of making a hyper-organization of knowledge with a lot of cards with facts.

It was not only Michel Foucault who understood documents as material building bricks in the social construction of the world. In the late 1960s and during the 1970s, American sociologists like Harold Garfinkel and Dorothy E. Smith developed similar theories about documentary practices and developed methods for studying these practices. These methodologies, the so-called ethnomethodology and documentary interpretation, were to a large degree based on the German sociologist Karl Mannheim, who formulated what he called "documentary or evidential meaning."^[13] The *documentary meaning* is the meaning the document reveals "unintentionally," which might be the meaning in a larger social context, or in other words, the documentary interpretation deals with the social role of the document which is not explicitly expressed in the document but nevertheless demonstrated by its place in the construction of a social world as a whole. Inspired by Garfinkel, Foucault, and others, the French sociologist Bruno Latour made similar studies of how scientific facts were constructed in the laboratory and has demonstrated this in several works, notably by the work together with Steve Woolgar from 1979. Latour and Woolgar made anthropological fieldwork in a scientific laboratory in California observing how *scientific facts* were constructed by making documents of different sorts, articles, monographs, diagrams, photos, etc. Since then a large field of science studies has emerged based on the same general document theory, stressing "[d]ocuments of various kinds come into play, but their connection with human agency varies according to the particular instance of interaction."^[14]

While the "professional" document theory developed by Otlet and others was focused on the knowledge more or less inherent in the documents and to make documents *about* something, then the general document theory developed by critical social scientists such as Foucault is much more about what the documents *are* and *do*.

This general approach to documents is followed by John Seely Brown and Paul Duguid in an essay from 1996. Here they presented a social theory of documents based on their own document oriented readings of a number of theorists in sociology, communication, and media studies.

They start out with questioning the "the widely held notion of the document as some sort of paper transport carrying preformed 'ideas' or 'information' through space and time" based on the "conduit" metaphor and belief of "information as 'in' books, files, or databases as if it could just as easily be 'out' of them." Brown and Duguid say:

As new technologies take us through major transformations in the way we use documents, it becomes

increasingly important to look beyond the conduit image. We need to see the way documents have served not simply to write, but also to underwrite social interactions; not simply to communicate, but also to coordinate social practices.^[15]

The research Brown and Duguid are using comprises works primarily by authors like Anselm Strauss, Benedict Anderson, Stanley Fish, and Bruno Latour. It is interesting to notice that apart from Latour, these scholars very little, if at all, use the notion of document in their writings. Brown and Duguid translate a number of related theories of social life into one theory of the role of documents in social life. These related theories are all characterized by an interest in how worlds, communities, and networks of humans and objects are created and constructed through shared documents.

Brown and Duguid develop a general document theory claiming that it is up to humans to discuss and decide if anything is a document. The Italian philosopher Maurizio Ferraris goes even further in his book on documentality,^[44,45] drawing on the works of Derrida and Foucault, presenting a whole document oriented philosophy, an ontology of documentality, claiming that the whole social world is based on documents and that there is nothing social outside texts or one may say documents. Ferraris says that social objects are made by acts of inscription, acts of registration. When you marry, it is being registered and people will know you are married. When you make a piece of art, it is registered either for yourself or for the public as a piece of art and you can look at it as art. Each certificate of marriage and each piece of art are characterized by an element of individuality (the names of the persons or the style) as well as by an element of regularity (standards and traditions).

DOCUMENT THEORY: A PART OF A MATERIALISTIC CRITIQUE OF LIS

One of the main arguments for leaving the documentation approach in the 1960s in the documentation/library field was that it was believed that when one got the computer, it was possible to go beyond physical barriers directly into cyberspace independent of time and place, having realized the Otletian dream of a world brain having everything in one place, in one format. In principle, this gives a possibility of focusing almost only on the user and his or her needs of information. It became a matter of formulating the information needs of the users, or in other words of observing how users thought, of getting a hold on their cognitive structures in order to match them with data structures in the computer.

While many definitions of document stress the physicality of the document, some might think that the document approach will become outdated when everything

becomes digital and gathered together into one big database. The reality is that the digital documents are no less physical than printed documents, but their type of physicality differs.

Following the historical approach, Michael Buckland has in a number of articles focused on the physical dimension, notably in the article "Information as thing" (1991). Buckland makes a distinction between "information-as-process," "information-as-knowledge," and "information-as-thing." Buckland believes that "information-as-thing," by whatever name, is of especial interest in relation to information systems because ultimately information systems, including 'expert systems' and information retrieval systems, can deal directly with information *only* in this sense.^[16] Buckland tells us that he deals with the ultimate condition for information, thingness, or material conditions for information. He wants to "clarify its meaning," "affirm the fundamental role of 'information-as-thing'" and by that "bringing theoretical order to the heterogeneous, ill-ordered fields associated with 'information science.'^[16] In this context, the notion of "document" is discussed as a possible concept for the "informative thing," being the core object for the whole field drawing very much on the contributions by Otlet and Briet.

In the classic article "What is a document" (1997), Buckland reviews a number of definitions of a document. Most authors, except for the Indian S.R. Ranganathan, are in fact in favor of a very broad definition of a document such as the general international definition from 1937: "Any source of information, in material form, capable of being used for reference or study or as an authority."^[17]

So one may ask whether the most important question is how far you can push the notion of document or whether it is the questions of the defining properties that may divide people. This brings us to another important issue, which Buckland brings up in his concluding comments:

One difference between the views of the documentalists discussed above and contemporary views is the emphasis that would now be placed on the social construction of meaning, on the viewer's perception of the significance and evidential character of documents.^[18]

This shifts the focus from being on the materiality of the document to a focus on the social and perceptual dimensions of a document, moving back to the semiotic tradition of "object-as-sign." After being told in the beginning that the materiality/physicality is the ultimate condition for dealing with information, it is surprising to read that one should not focus so much on the physical form but give more priority to the social function and how it is perceived by people in different social settings. According to Buckland, this must be seen in the light of the digital technology:

any distinctiveness of a document as a physical form is further diminished, and discussion of "What is a digital

document?” becomes even more problematic unless we remember the path of reasoning underlying the largely forgotten discussions of Otlet’s objects and Briet’s antelope.^[19]

This apparent paradox of where to put emphasis in document theory can be understood better when we see the work by Buckland not only as a materialistic critique of the dominating information paradigm in LIS, but also as part of several attempts to formulate one or more socially and culturally oriented alternatives in LIS since the early 1990s. In addition to Buckland, this has been dealt with by North American scholars like Ronald E. Day and Bernd Frohmann, and Scandinavian scholars like Birger Hjørland and Vesa Suominen.

Drawing on many general theories from philosophy, especially Benjamin, Foucault, Derrida, Deleuze, Peirce, etc. it has been a major theme for Ronald Day in several of his works to demonstrate the metaphysical character of the dominating information paradigm, which perceives the idea of information as something abstract, existing in our heads or in the air, and thus ignoring the objects, the “information-as-things” as the material basis for information. At the same time, Day has shown how the material qualities are dependent on their cultural and social conditions and cannot be separated from them. In this perspective, the notion of document and the works by Otlet and Briet become essential.

Bernd Frohmann started out in the early 1990s by making a number of critical inquiries on some of the dominant paradigms, in order to present the alternative paradigm of a materialist approach to documentary systems formerly known as information systems. Frohmann established this as his major field through several contributions.

Like Day, Frohmann draws on several larger theories not only to make a critique of the information paradigm, but also to present a paradigmatic alternative. In an article from 2000, Frohmann argues in favor of using the ideas of Foucault regarding materiality providing a possibility for studying what documents do in social life.^[20]

The most important contribution by Frohmann is his monograph from 2004, where he manages to present a full-scale paradigmatic alternative to the dominating LIS paradigms, based on a complex document theory. Frohmann defines documents as “different material kinds of temporally and spatially situated bundles of inscriptions embedded in specific kinds of cultural practices.”^[21] What interests Frohmann is how documents work in different situations, how they function as stabilizing factors in social communities, like the role of scientific journals in scientific communities. In this way, he follows the document theory developed by Foucault and other critical philosophers and social scientists like Garfinkel, Smith and so on as has been mentioned above.

A similar approach has been taken by a number of Scandinavian scholars. Birger Hjørland recommends that “the

object of study [changed] from mental phenomena of ideas, facts and opinion, to social phenomena of communication, documents and memory institutions.”^[22] Hjørland claims that the most important thing is that “the intrinsic natures of these objects are relatively irrelevant.”^[22] They only become documents once they are assigned an informative value by a collective or domain, as Hjørland has called the communities involved in the decision whether a thing becomes a document or not. Here we are told that documents are used as stabilizing means in our society, being “relatively stable forms of practice”^[23] creating a sociocultural document theory along the lines of the work by Ron Day, Vesa Suominen, and notably Bernd Frohmann.

The Danish scholar Jack Andersen attempts to develop a theory of the social organization of documents and knowledge in society, and it is the German social theorist, Jürgen Habermas, who functions as Andersen’s primary theoretical background, especially his work on the Public Sphere. The theory of the Public Sphere can be considered a social theory stressing the role of various communication media in the organization and transformation of modern societies, in the formation of public opinion and how it relates to the capitalist mode of production.^[24] This understanding enables Andersen to translate the theory of public sphere into a theory of the social organization of documents and knowledge in society. In this way, it creates the basis for saying:

What is crucial about this variety of document genres operating in society and state is that they organize the communicative activities of the various spheres and domains. The spheres generate documents in order to act within and in-between the particular spheres and are thus forming a communicative action.^[25]

Therefore, the theory of the social organization of documents in society as formulated by Andersen explains the need for and potential advantages of the diversity of documents, in contrast to Otlet’s interest in bringing all documents of the world into one format.

THEORIES ON DOCUMENTS IN A DIGITAL AGE

David Levy, who already in 1988 launched the idea of having a large program for document research, wrote in 2001 about how documents may make sense in a digital age. According to Levy, documents “are, quite simply, talking things. They are bits of the material world—clay, stone, animal skin, plant fiber, sand—that we’ve imbued with the ability to speak.”^[26] Levy relates this function to the theory by Bruno Latour on delegation of responsibility not only to other humans through networks, but also to inanimate objects.

After having presented a very broad definition of documents, David Levy wants to look more closely “at the

nature of digital documents” with the hope of sorting out what is new and what is not.^[27] He says: “Digital materials are made up of both the *digital representation* and the *perceptible forms* produced from it.”^[28]

As a result of all these threads of invention and adaption, a global infrastructure for the production, distribution, and consumption of digital documents is now emerging.^[29]

This leads to one of the important issues: “How to guarantee fixity and permanence?”

One may ask: What is meant by being the same, How do you identify the likeness of two documents? This is a theme that has attracted a number of scholars and which leads to a number of questions concerning the nature of a document. If you identify two documents as being alike, you must be able to define the criteria for them being the same. In the article “Towards identity conditions for digital documents,” Allen Renear and David Dubin deal exactly with this problem, wondering why so little has been done in document theory since it is crucial for dealing with digital documents.

As a result, not only is this critical concept under-theorized, but progress on a number of important problems—including preservation, conversion, integrity assurance, retrieval, federation, metadata, identifiers—has been hindered. The development of identity conditions for a particular kind of entity is not something separate from, let alone subsequent to, defining that entity, so we cannot *begin* our development of identity conditions with an explicit definition of what we mean by “document”. [...] By *document*, then, we refer to the abstract symbolic expression that may be physically instantiated repeatedly and in various media. This use corresponds more or less to the FRBR term “expression”^[17] and has the colloquial synonym “text.” Although now fairly common, this sense of “document” does compete with another well established and closely related use of the term [...] to the physical carrier with its instantiated inscription.^[5] Terminological choices in this area are difficult, but we believe our usage is consistent with common and emerging practice in publishing and information science.^[30]

They touch one of the core issues in document theory regarding competing use of the notion of a document as referring either to the physical instantiation or the abstract expression and one could add the understanding of a document as a sociocultural construction.

This theoretical challenge has been dealt with in one of the largest theoretical projects regarding document theory, the French network-based project, RTP-doc: Recherche thématique pluridisciplinaire (<http://rtp-doc.enssib.fr/>). It illustrates that the document approach has survived more prominently in the Francophone world, in contrast to the Anglophone world. The group consists of scholars from many different disciplines enabling an interdisciplinary project on document theory. It was decided to approach the concept of document from three angles: first,

a document as form, emphasizing the materiality of document. The second perspective was to see the document as a sign, focusing on the way the document may make sense, being meaningful, and being based on an intention. The third approach concerns how a document is a social object, depending on its position in a social context.^[31]

GENERAL INTEREST FOR DOCUMENT THEORY: A COMPLEMENTARY APPROACH TO DOCUMENT THEORY

In 1996, a program in documentation studies at the University of Tromsø, Norway was established on all levels from an undergraduate to Ph.D. program.

Before the program started, a committee of librarians and faculty members from different disciplines formulated the general conceptual framework for the program, at this point not knowing very much about Otlet or Briet. The main reason for choosing the name documentation studies was not based on a theoretical interest in making a new paradigm within LIS, but on a much more pragmatic and general political interest in relation to the establishment of a National Library in Norway in 1989 and at the same time the launching of a very broadly defined act of legal deposit in Norway, including documents of all kinds, printed matter, broadcast television, radio and movies, and last but not least including the new digital documents on the Web changing all the time! One may say that it made the Otletian ideal explicit and challenged the Norwegian Library system in two fundamental ways, regarding open and free access and preservation. One challenge was posed by the complicated copyrights connected to interests of users as well as producers of all the documents and the other challenge was no less than about the “intrinsic” nature of the documents, how to preserve the documents making them available at the right time for any user in all future.

This practical challenge called for a so-called complementary approach to document theory formulated by Niels Windfeld Lund.^[32,33] It is not a question of making a synthesis, but to view the document from three complementary angles, all together making a complete description. That means that the document does not partly carry one of these three features, but it is 100% a physical phenomenon, 100% a social phenomenon, and 100% a mental phenomenon. Any document is a physical object as well as a social and mental object. The core issue is how these dimensions are interacting with each other in different ways, depending on the physical, social, and mental environments in which documentation takes place, for example, health care, the arts, business, local as well as virtual subcultures, politics, and so on.^[34] Instead of a belief in making one format for documentation, document theorists today are focusing on the diversity of documents and studying the wide range of problems related to

processes of documentation and the resulting documents posed by concepts of “authorship,” “identity,” “intellectual property,” as well as by document retrieval, annotation, principles of preserving digital documents, multimedia documents, politics of documentation, and many more.^[31]

Since 2003, The Annual Meeting of the Document Academy, DOCAM,^[35] has been one of the main fora for the “neo-documentalist movement.”^[36] The Document Academy is an international organization discussing document theory as well as presenting a diversity of document-oriented studies in their annual meetings. One of the key discussions has been where and how far can you take and apply the document approach: does it cover orality,^[37,38] literature and movies,^[39,40] and museums^[41]?

Another recent tendency is that the notion of document is being used as concept and focus in other disciplines than Library and Information Science like anthropology,^[42] medical informatics/telemedicine,^[43] and philosophy.^[44]

Document Type Definition (DTD)

Judith Wusteman

*School of Information and Communication Studies, University College Dublin,
Dublin, Ireland*

Abstract

Document Type Definitions (DTDs) are schemas that describe the structure and, to a limited extent, the content of XML and SGML documents. At its inception, the XML standard inherited the DTD from SGML as its only schema language. Many alternative schema languages have subsequently been developed for XML and are widely used in data-centric applications. But the DTD is still alive and actively used to define some narrative-based document types, particularly journal articles. This entry describes the basic syntax of the DTD and compares it to its two main rivals: W3C XML Schema and RELAX NG.

INTRODUCTION

Despite their names, Extensible Markup Language (XML) [ref XML entry] and its predecessor, Standard Generalized Markup Language (SGML) [ref Markup languages entry], are not languages *per se*. Rather, they are systems for creating customized markup languages. As XML is a subset of SGML, many of the comments made in this entry will be relevant to both. However, given that the SGML standard has now been largely superseded by XML, this entry will concentrate on XML. Some examples of XML languages of particular interest to the Library and Information Science community are listed in Table 5.

The set of rules that defines an XML or SGML language is called a schema. Schemata describe the structure and, to a varying extent, the content and semantics of documents that conform to specific languages. For example, a schema for XHTML 1.0 Strict, would, among other things, identify which elements and attributes are allowed or required in an XHTML 1.0 Strict document.

There are several common formats used to express schemata; such formats are referred to as schema languages. The schema language designed to express SGML schemata was the Document Type Definition (DTD). At its inception, the XML standard inherited the DTD as its only method of defining schemata. Many alternative methods have subsequently been developed for XML, the most influential of these being the W3C XML Schema Definition (XSD)^[1] and RELAX NG.^[2] These latter two schema languages are widely used in data-centric applications. However, despite its rivals, and continuous predictions of its demise, the DTD is still alive and actively used to define narrative-based document types, such as e-journal articles, prose, poetry, and archival finding aids, as is illustrated in Table 5.

This entry describes the basic syntax of the DTD and explains some of its more common features, such as elements, attributes, and entities. Methods of

associating DTDs with XML documents are mentioned, along with an explanation of the function of validating parsers. This is followed by a comparison of the DTD with its two main rivals: W3C XML Schema and RELAX NG. Sample XML languages that employ each of these schema languages are listed. They demonstrate how the DTD has been losing ground to its rivals but also that it is still an important schema definition format in some domains.

VALIDATING XML INSTANCES

XML documents are commonly referred to as XML instances. The software that reads and interprets these instances is called an XML parser. The parser may be contained within another piece of software, such as a browser or an editor, or it may exist independently. Parsers come in two main varieties: nonvalidating and validating. Nonvalidating parsers simply check whether XML instances are well formed, that is, whether they obey basic constraints such as including a document element (previously known as a root element) that contains all other elements [ref XML entry]. Validating parsers also check whether instances are valid, that is, whether they conform to the rules of a schema, for example, a DTD.

DTD SYNTAX

Fig. 1 illustrates an example of a well-formed XML instance, prefaced by the relevant DTD (within square brackets). This simple DTD comprises a series of element and attribute declarations. The first thing to notice is that a DTD is not written using XML document syntax; rather, it uses a distinctive syntax of its own.

Fig. 1 An XML instance of a simplified book catalogue entry plus DTD.

Elements

The basic structure of an element declaration is as follows:

```
<!--ELEMENT elementName (content model)-->
```

Note that reserved words, such as ELEMENT, must appear in upper case. The right-hand side of the element declaration, referred to as the content model, details what combinations of child elements and plain text (indicated by #PCDATA) are permitted to appear in the element in question and in what order they may appear.

Sequence within the content model is indicated by the comma. For example, in the following element declaration, the *authors* element is followed by *title*, which is followed by an optional *publisher* element, and so on:

```
<!--ELEMENT entry (authors, title, publisher?, isbn+, notes*, related, location)-->
```

The occurrence indicators +, ?, and *, listed in Table 1, define how many times an element (or a more complex pattern within parentheses) can be repeated. For example, an *entry* may include

- One optional *publisher*
- At least one *isbn*, but it can have any number
- Any number of *notes* or none at all.

Options are indicated by a vertical bar. For example, in the following element declaration, the *location* element may contain either the *shelved-at* or the *url* element, but not both.

```
<!--ELEMENT location (shelved-at | url)-->
```

Mixed Content

When an element can contain a mixture of plain text and child elements, the content is referred to as “mixed.” For example:

```
<!--ELEMENT notes (#PCDATA | reference)*-->
```

Table 1 Occurrence indicators.

Occurrence indicator	Meaning
?	Optional
+	Must appear one or more times
*	Can appear 0 or more times
(no indicator)	Must appear once

Here, the *notes* element may contain any number of *reference* elements interspersed with the plain text. In the sample instance, it contains two *reference* elements. The plain text comprises the words “Includes bibliographic references,” “and,” and a full stop.

SGML allowed a range of mixed content types. However, as part of a concerted effort to make the XML standard as simple as possible, there is only one form of mixed content allowed in XML. The basic structure is as follows:

```
<!ELEMENT elementName (#PCDATA | childElementA
| childElementB | ...) *>
```

Limitations of the Element Declaration

Some grammatical expressions are not easily expressible via a DTD. For example, number ranges and unordered content may require complex or inelegant element declarations, as illustrated by the following examples.

Indicating a number range

To define the *authors* element as having between one and five child elements called *name*:

```
<!ELEMENT authors (name, name?, name?,
name?, name?)>
```

Indicating unordered content

To imply that the child elements *authors*, *title*, and *publisher* must all appear in element *entry* but can appear in any order:

```
<!ELEMENT entry ((authors, title, pub-
lisher) |
(authors, publisher, title) |
(title, publisher, authors) |
(title, authors, publisher) |
(publisher, authors, title) |
(publisher, title, authors)) >
```

In the real world, this would probably be modeled as

```
<!ELEMENT (authors | title | publisher) +>
```

which allows the unordered nature of the content model to be validated. The numerical aspect (one of each and only one), however, would need to be enforced via an additional schema or programming language, such as Schematron.

Attributes

Attributes appear within element start tags and supply additional information, or metadata, about the element that is not part of normal document content. Since the inception of SGML, there has been heated discussion concerning when to use elements and when to use attributes. There are no fixed rules, but Ogbugi^[3] provides some useful guidelines.

Table 2 Attribute types.

Attribute type	Explanation of attribute value
CDATA	Character Data is plain text, that is, text that does not contain markup
Enumerated list of form (x y z)	One of a predefined set of values
ID	A unique identifier
IDREF	Reference to a unique identifier
IDREFS	List of references to unique identifiers
ENTITY	An entity
ENTITIES	A list of entities
NMTOKEN	A valid XML name
NMTOKENS	A list of valid XML names
NOTATION	The name of a notation

The general structure of a declaration for one attribute is as follows:

```
<!ATTLIST element-name attribute-name attribute-type
default-value>
```

One attribute declaration may be used to define any number of attributes relating to a single element. For example, if two attributes were to be defined for one element, the format would be

```
<!ATTLIST element-name attribute-name attribute-
type default-value attribute-name attribute-type default-
value>
```

Table 2 lists all of the allowable types of attribute. CDATA is probably the most commonly used attribute type; enumerated lists, ID, IDREF, and IDREFS are also common. Possible *default values* for attributes are listed in Table 3.

Examples

Attribute of type CDATA

In DTD:

```
<!ELEMENT url EMPTY>
<!ATTLIST url href CDATA #REQUIRED>
```

In instance:

```
<url href="http://www.location.com"/>
```

An empty element, indicated by the / at the end of the tag, has no content, thus no close tag. The sole function of an empty element is often to be the placeholder for an

Table 3 Attribute default value types.

Default-value	Explanation
Value	Attribute has specified default value
#REQUIRED	Attribute must always be included
#IMPLIED	Attribute is optional
#FIXED value	Attribute must always have specified value

attribute, as in this example. The `#REQUIRED` default value for attribute `href` indicates that this attribute is compulsory for the `url` element. There could be no sensible default value for `href` but the DTD author still wants to force the attribute to be present.

Attribute of type enumerated list

In DTD:

```
<!ATTLIST isbn version (isbn-10 | issb-13)
"isbn-10">
```

In instance:

```
<isbn version="isbn-13">978-0071346214
</isbn>
```

The attribute declaration indicates that the default value of attribute `version` is `isbn-10`. Defaults may be left out in the document instance. Thus,

```
<isbn>007134621X</isbn>
```

has the same meaning as

```
<isbn version="isbn-10"> 007134621X
</isbn>
```

Attributes of type ID and IDREFS

In DTD:

```
<!ATTLIST entry id ID #REQUIRED>
<!ATTLIST related related-ids IDREFS
#IMPLIED>
```

In instance:

```
<entry id="X123">
<related related-ids="X345 X456 X567"/>
```

Attribute type ID facilitates attribute values that are unique and nonrepeatable throughout an XML instance. In the example, each entry is given a unique identifier via the `id` attribute. It is common, but not compulsory, to use `id` as the name of an attribute of type ID.

The attribute `related-ids` lists the identifiers of all entries related to the current entry. The identifiers listed in an attribute of type IDREF or IDREFS must appear within the current instance. Thus, this instance would only be valid if the three entries, referenced by identifiers `X345`, `X456`, and `X567`, were listed in the same document as entry `X123`.

An entry may not have any related entries; thus, the use of the default value `#IMPLIED`. The latter implies that the inclusion of an attribute value in the document instance is optional.

Entities

The basic concept of an entity is simple: it is shorthand for a larger piece of text or an alias for some other form of data, for example, a special character. When an XML parser comes across a reference to an entity, the reference is replaced with what it represents. Entities can be divided

into two main groups: general entities, which provide short cuts for use within an XML instance, and parameter entities, which perform the same function for use within a DTD. An entity must be defined in the DTD before any reference is made to it. Because of this, it is good practice to place all entity declarations at the beginning of the DTD.

General entities

There are three types of general entity: internal parsed, external parsed, and external unparsed.

Internal parsed general entities: The data referenced by the entity is internal to the DTD. For example:

```
<!ENTITY rights "All rights reserved">
```

The inclusion of the entity reference `&rights`; in a document instance results in the text “All rights reserved” being placed in the text at that point when the instance is parsed.

External parsed general entities: The data referenced by the entity is in a file external to the DTD, as indicated by the reserved word, `SYSTEM`. For example:

```
<!ENTITY rights SYSTEM "rights.txt">
```

The inclusion of `&rights`; has a similar effect as in the previous example, but in this case, the contents of the file `rights.txt` is placed in the text.

External unparsed general entities: These entities enable the embedding of non-XML content in XML documents. For example, such an entity could be used to include a movie file in a document instance. Such entities are described as “unparsed” because the XML parser does not look at their contents.

Using general entities to represent special characters.

Unicode provides a unique number for each text character in most of the world’s writing systems. For example, the character `â` is represented by the number 226.

To include a Unicode character that cannot be typed directly via the keyboard, an internal parsed general entity reference may be used in the XML instance. For example, the character `â` may be represented by the entity reference `â`. Given that the latter refers to a specific character, it is described as a character entity reference. Assuming that a character set containing the glyph is available on the computer in question, this will result in the character `â` being placed in the text when the instance is parsed.

The general entity reference `â` does not need to be defined in the DTD because all XML processors are required to support Unicode. However, if, instead of this numeric reference, the use of a mnemonic character entity reference such as `â` is preferred, the latter should be defined in the DTD using an internal parsed general entity as follows:

```
<!ENTITY acirc "&#226;">
```

Table 4 Built-in general entities.

Built-in entity	Character represented
<	<
>	>
&	&
"	"
'	'

There are five mnemonic character entities that do not have to be declared in the DTD because they form part of the definition of XML. They are listed in Table 4.

Parameter entities

Parameter entities are similar to general entities but are for use in the DTD itself. As with general entities, parameter entities can be internal or external but, unlike general entities, they are always parsed. In the real world, complex DTDs are rarely presented as a simple list of element and attribute declarations as illustrated in Fig. 1. Rather, a combination of internal and external parameter entities are used to modularize the DTDs.

Internal parameter entities: These can be useful if an element or attribute content model is repeated regularly or if the model is complex. The following entity declaration is taken from the ANSI/NISO Z39.96-2012 JATS: Journal Article Tag Suite (JATS):^[4]

```
<!ENTITY % app-model "(%sec-model;,  
permissions?)">
```

This defines a parameter entity describing the content model for the appendix of a journal article. Note that the syntax for parameter entity declarations is the same as for general entities, with the addition of a % symbol after the reserved word ENTITY. The parameter entity *app-model* is subsequently used in the element declaration for the appendix. Again, the syntax for parameter entity references is similar to that for general entity references but includes % instead of &.

```
<!ELEMENT app %app-model;>
```

In this example, the value of the parameter entity itself includes a reference to another parameter entity: *%sec-model*. The use of nested parameter entity references is a common method of modularizing large DTDs.

External parameter entities: External parameter entities are also used to modularize DTDs. For example, the following declaration occurs near the beginning of the XHTML 1.0 DTD:

```
<!ENTITY % HTMLlat1 PUBLIC "-//W3C//  
ENTITIES Latin 1 for XHTML//EN"  
"xhtml-lat1.ent">
```

The keyword PUBLIC indicates that what follows is the formal public identifier for the entity. This identifier is followed by the name of the file containing the entity's

content, namely *xhtml-lat1.ent*. In the XHTML 1.0 DTD, this entity declaration is immediately followed by an invocation of the entity:

```
%HTMLlat1;
```

As a result, when the DTD is parsed, the contents of the file *xhtml-lat1.ent* are placed at this point within the DTD.

The file *xhtml-lat1.ent* contains declarations for several dozen mnemonic character entities, for example:

```
<!ENTITY Agrave "&#192;">  
<!ENTITY Aacute "&#193;">  
<!ENTITY Acirc "&#194;">  
<!ENTITY yen "&#165;">
```

Thus, by using the parameter entity, all the mnemonic character entities defined in file *xhtml-lat1.ent* are available for use within document instances. Incorporating external files of general entity declarations that define useful mnemonic character entities is a common use of parameter entities.

Readability

If the reader is familiar with basic DTD syntax, a well-written DTD can be relatively simple to interpret. Good human readability is one of the advantages that DTDs have over schema languages such as the W3C XML Schema and is one of the reasons why the DTD has not yet been superseded. It is therefore important to ensure that DTDs are as readable as possible, for example, by using meaningful element and attribute names and including a liberal number of comments. In fact, many DTDs contain far more comments than code. The syntax for comments is as follows:

```
<!-- Comments go here -->
```

Apart from listing entities before using them, there are no rules concerning the order of declarations in DTDs. However, authors should attempt to ensure that DTDs are clear and logical to human readers.

DOCUMENT TYPE DECLARATIONS

A DTD is associated with an XML instance via a Document Type Declaration (DOCTYPE). The latter is placed after the XML declaration at the beginning of the XML file, as illustrated in Fig. 1.

The most widely recognized DOCTYPEs are those related to HTML as they appear—or should appear—at the start of every HTML file. Because HTML5 is not an XML language and so not definable by a DTD, its DOCTYPE is very simple:

```
<!DOCTYPE html>
```

Table 5 Sample XML languages of particular interest to the Library and Information Science community.

Language	Original format	Definitive form	Other formats available	Comments	Website
NISO Journal Article Tag Suite (JATS)	DTD	DTD	XSD RELAX NG	Almost everyone is still using the DTD for production and publishing ^a	http://jats.nlm.nih.gov/
Text Encoding Initiative (TEI)	DTD	ODD (One Document Does it all)	Does ODD can be compiled into DTD XSD RELAX NG	DTD use gradually giving way to RELAX NG and XSD	http://www.tei-c.org/
Encoded Archival Description (EAD)	DTD	DTD	XSD Relax NG	Some migrated away from DTDs, but they are still widely used	http://www.loc.gov/ead/
CrossRef	DTD	XSD		Based on (The Making of America II, MOA2) DTD	http://www.crossref.org/
Metadata Encoding and Transmission Standard (METS)	XSD	XSD			http://www.loc.gov/standards/mets/
Metadata Object Description Schema (MODS)	XSD	XSD			http://www.loc.gov/standards/mods/
ETD-MS: Electronic Theses, and Dissertations Metadata Standard	XSD	XSD			http://www.ndltd.org/standards/metadata
Visual Resources Association (VRA) Core	XSD	XSD			http://www.loc.gov/standards/vracore/
Docbook	DTD	RELAX NG (with integrated Schematron rules)	DTD XSD		http://www.docbook.org/
OASIS Darwin Information Typing Architecture (DITA)	DTD	DTD	XSD RELAX NG		http://dita.xml.org/
XHTML 1.0	DTD	DTD	XSD RELAX NG	XHTML 2.0 abandoned at Working Draft stage in favor of HTML5	http://www.w3.org/TR/xhtml1

Key: XSD, W3C XML Schema.

^aSee http://www.niso.org/workrooms/sts/for_ongoing_efforts_at_standardization.

```
<?xml version="1.0"?>
<!DOCTYPE catalogue SYSTEM "http://www.catalogue.com/catalogue.dtd"
[
<!ENTITY Acirc "&#194;">
<!ENTITY Atilde "&#195;">
<!ENTITY Ccedil "&#199;">
]>
XML instance follows
```

Fig. 2 An XML instance with internal and external DTD subsets.

XHTML 1.0 Transitional, on the other hand, is an XML language and the structure of its DOCTYPE reflects this:

```
<!DOCTYPE html PUBLIC "-//W3C//DTD
XHTML 1.0 Transitional//EN"
"http://www.w3.org/TR/xhtml1/DTD/
xhtml1-transitional.dtd">
```

In this latter DOCTYPE, *html* is the DTD's document element, that is, the element that must contain all other elements in documents that conform to this DTD. The document element is followed by the keyword PUBLIC, then the formal public identifier, and, finally, a Uniform Resource Identifier locating the DTD. As can be seen, there are parallels between the structure of document type declarations and external parameter entities.

In this example, the DOCTYPE simply identifies the document element and provides information to identify and locate the relevant DTD. It is also possible for the DOCTYPE to include the DTD, or an *internal subset* of the DTD. In Fig. 1, the DTD is included within the DOCTYPE between square brackets. In Fig. 2, the main DTD, referred to as the *external subset*, is in file *catalogue.dtd* at <http://www.catalogue.com/>. An internal subset, comprising three mnemonic character entity declarations, is contained within the DOCTYPE. The declaration of mnemonic character entities is a common use of an internal subset within an XML file. As this method is recognized by all schema languages, this limited use of DTDs is often used in conjunction with other schema languages.

VALIDATING PARSERS

It is compulsory to include a DTD with every SGML instance. With XML, it is optional; many XML documents are not related to any form of schema. This is appropriate for some uses of XML, particularly one-off machine-to-machine communications that are not meant to be archived. But it is not appropriate for documents that require consistency of markup. In addition, it is important to note that DTDs often do more than provide validation rules for XML instances. They may also add to the document's information set, or *infoset*, that is, the information provided by the document. For example, they may define entity references or provide default values for attributes.

Parsers vary as to how they deal with internal and external DTD subsets. Although nonvalidating parsers do not check documents for validity, some do read the external subset of the DTD, process default attributes, and expand entities. And all conforming parsers should do this for internal subsets. When receiving a document from a third party, it is preferable to use a parser that performs all of these tasks. However, when authoring documents, it is prudent to assume that the receiving parser may not read the DTD. Thus, the DTD should not be used to add to the infoset.^[5]

ALTERNATIVE SCHEMA LANGUAGES

W3C XML Schema Language

SGML and the DTD were designed to enable the markup of document-centric applications: full-text documents such as technical manuals, journal articles, prose, poetry, and drama. They were not designed for data-centric documents. XML was intended to be a simplified web-enabled version of SGML. When XML became a W3C standard in 1998, the DTD was adopted as XML's only schema language.

However, it soon became clear that the most widespread use of XML would be in data-centric applications such as eCommerce and Web Services. And, for XML to achieve its full potential in such applications, a more data-centric method of describing document validity was required. In particular, finer control was needed over the validity of element content and, to a lesser extent, of attribute content.

So, in 2001, the W3C XML Schema language, commonly, if confusingly, known as XML Schema, became a W3C standard. One of the two main advantages of XML Schema is the powerful data typing facilities for element and attribute values. There are 40 two different types that can be assigned to an attribute or element, including integer, date, string, qualified name, positive integer, and so on. Users can also define their own types, for example, currencies, colors, phone numbers, and so on. The other main advantage of XML Schema over DTDs is the support for namespaces, which is a method for avoiding naming conflicts when more than one XML language is used in the same instance. Datatype declarations and namespaces were both added to DTDs as part of the

Document Schema Definition Languages (DSDL).^[6] However, no developer of XML software has ever showed an interest in implementing these aspects of DSDL.^[7]

The W3C XML Schema language has come in for criticism due to its verbosity and its lack of human readability. But, at this stage, it is well established and well supported by XML software. Further, the schemata of many data-centric applications are not primarily intended for human consumption but for machine-to-machine communication, thus human readability is not paramount. For such applications, software-generated graphical views of XML Schemas are generally sufficient for the end user.

RELAX NG

Whereas the use of XML Schemas is currently best practice for data-centric applications, best practice for narrative-centered applications is far less clear. The main contender, RELAX NG (which stands for REgular LAnguage for XML Next Generation and is pronounced “relaxing”) is widely regarded as technically superior to DTDs. It can do almost everything that DTDs can do (apart from defining entities and notations), almost everything that XML Schemas can do (apart from defining its own data types) and quite a few things that XML Schemas cannot do. What is more, RELAX NG schemas are easy to read, easy to write, and easy to extend. They can represent more powerful content models than can DTDs and, unlike the latter, they support namespaces.

However, RELAX NG has not yet displaced the DTD in some domains, for example, the publishing industry. This is due to a combination of reasons. Because RELAX NG is not a W3C standard, it has not received the same level of support as XML Schema. Tool support, although growing, is not yet adequate for some industries to consider its use. There is also the issue of legacy data and whether the advantages of RELAX NG constitute a good enough reason for a potentially costly migration.

Using More Than One Schema Language

The validation of XML documents is too diverse to rely on a single schema language across all domains. It is likely that the medium term future will see the use of a range of schema languages, particularly XML Schema, RELAX NG, DTDs, each potentially in combination with Schematron.^[8] Increasingly, applications do not rely on one document model to provide all the information necessary for validation. For example, DTDs may provide the tag set but additional rules about how these tags may be used is enforced via another schema language, such as Schematron, or via a traditional programming language

Table 6 Advantages of the DTD.

A simple, mature, robust, well-tested standard
An integral part of the XML recommendation, so wide tool support
Includes entity definition (not available in RELAX NG and XML Schema)
Supports widely used practices in industries such as publishing
Easy to author and maintain
Most appropriate for narrative documents, particularly those with considerable mixed content
Designed for human consumption; easy to read
Good support for validation of element and attribute structures
Easily modularized
Considerable legacy data exists

such as Perl, JavaScript, XSLT, Python, Java, C#, C++, or Ruby.

Table 5 lists some sample XML languages of particular interest to the Library and Information Science community, along with their normative, or definitive, schema form and any other schemas available. The trend of using one schema language to produce the normative version of a schema and then auto-generating other versions from it is likely to increase. For example, both JATS and Encoded Archival Description [ref EAD entry] are available in DTD, XML Schema, and RELAX NG versions. In both cases, the DTD is the normative form.

It is interesting to note that, although the DTD was the original schema language for many applications, the normative version is now often in an alternative schema language. For example, the master version of the Text Encoding Initiative (TEI) [ref TEI entry] is now in ODD (One Document Does it all) format. This may be compiled into schemas in DTD, W3C XML Schema, or RELAX NG format as required. Rahtz^[9] summarizes the position of the competing schemas in TEI (as of August 2014) as follows: “Periodically, the TEI Technical Council asks itself “do we need to maintain TEI DTDs any more? doesn’t everyone use RELAX NG or W3C Schema now?”. The answer is (usually) always “yes, we do, some people have DTD technology embedded in their workflow.”

Tables 6 and 7, respectively, summarize the advantages and disadvantages of DTDs.

Table 7 Disadvantages of the DTD.

Non-XML syntax
No data typing for element content
Limited data typing for attribute content
No <i>implemented</i> support for namespaces
No support for newer features of XML (i.e., constraining the number of element occurrences)
Some common grammatical expressions are not easily expressible

CONCLUSION

The DTD schema defines the structure and, to a limited extent, the content of conforming XML documents. At the turn of the twenty-first century, it appeared that DTDs would soon be obsolete, to be imminently superseded by W3C XML Schema and RELAX NG. However, this did not happen. The move away from DTDs has been significant, particularly for data-centric applications, where the W3C XML Schema language has all but won the day. But the move has not been universal. Although alternative schemas may now be made available for many document-centric XML applications, this does not mean that users are actually employing them. In the medium term, it is likely that DTDs will come to be regarded as a legacy technology in many domains. But, in some industries, the DTD will continue to be widely used for some time to come.

Dublin Core Metadata Initiative (DCMI): A Personal History

Stuart L. Weibel

Office of Research and Special Projects, OCLC Research, Dublin, Ohio, U.S.A.

Abstract

This entry is a personal remembrance of the emergence and evolution of the Dublin Core Metadata Initiative from its inception in a 1994 invitational workshop to its current state as an international open standards community. It describes the context of resource description in the early days of the World Wide Web, and discusses both social and technical engineering brought to bear on its development. Notable in this development is the international character of the workshop and conference series, and the diverse spectrum of expertise from many countries that contributed to the effort. The Dublin Core began as a consensus-driven community that elaborated a set of resource description principles that served a broad spectrum of users and applications. The result has been an architecture for metadata that informs most Web-based resource description efforts. Equally important, the Dublin Core has become the leading community of expertise, practice, and discovery that continues to explore the borders between the ideal and the practical in the description of digital information assets.

IN THE BEGINNING

In 1994, Internet search engines were virtually unknown, “resource description” meant library catalogers in technical services departments, and the idea of harvesting and indexing billions of pages of electronic resources was too fantastic for most people to contemplate. Information assets, if they were cataloged at all, were described using a collection of library content and format standards known as MARC, and even the description of traditional paper resources was typically backlogged in overburdened cataloging departments.

Web-scale harvesting and indexing has long since carried the burden of open online search, but many electronic resources (e.g., images, services, or applications) have no suitable harvestable surrogates. Metadata—information about other information resources—is intended to fill this gap, providing explicit descriptions to support many administrative, commercial, and management needs. Governments use metadata to connect legislative mandates and citizens, and target services to those who need them. Electronic commerce requires metadata to match search queries with products. Publishers need metadata to create product catalogs and manage rights. Corporations use metadata to organize and integrate documentation, business processes, reporting requirements, and products. Thus, descriptive metadata remains a key aspect of resource management, on the open Web as well in organizational intranets. As the importance of images grows in online media, so too does the metadata that describes such images. Normally-sighted people need image metadata to search for images. For the visually impaired, an image without a description is worse than no image at all—an unfulfilled promise of inaccessible content.

As the Web exploded on our desktops, it was evident that MARC of electronic resources would be too complex and costly, and might not be suitable for many electronic resources in any case. Might there be a simpler alternative for describing Web assets that does not require the experience of expert catalogers?

That was the question posed over coffee between sessions at the Second International World Wide Web meeting in Chicago in October of 1994. Joseph Hardin, Yuri Rubinski, Eric Miller, Stuart Weibel, and Terry Noreault were bemoaning the fact that it was difficult to find a given item among the nearly 500,000 addressable resources on the World Wide Web (never mind how many single sites of that size there are now). Joseph Hardin was leader of the software development team at the National Center for Super Computer Applications (NCSA) that developed Mosaic, the first cross-platform Web browser. The late Yuri Rubinski founded SoftQuad, and is credited with popularizing SGML, the precursor to XML. Terry Noreault was then director of the OCLC (Online Computer Library Center) Office of Research, and Eric and I were colleagues in the Office of Research. Why not convene a group to look at the question systematically? Eric Miller and I spent the next few months organizing such a meeting, driven by the timeline of the next Web conference to be held the following April in Darmstadt, Germany.

THE OCLC–NCSA METADATA WORKSHOP

The OCLC and NCSA (the National Center for Super Computer Applications at the University of Illinois) cosponsored this first meeting. We invited people from

three general categories: content specialists, Internet technologists, and librarians (later we thought of these groups affectionately as the “freaks, the geeks, and the people with sensible shoes”). Fifty-two people attended that first two and a half day workshop in March of 1995. We started with the notion of “document-like object (DLOs)” on the Web—something familiar to give us a mental image without being too precise about what we might want to describe. This vagueness was comforting in our early, unbounded expectations, but sometimes confounded later efforts to bring description standards to bear in actual applications. We stopped talking much about *DLOs* and often struggled with the differences among Web resources and how they should be characterized to enhance their discoverability.

What we hoped to do was to characterize conventions for resource description—to give people (authors, Web site managers, content providers) a set of common descriptive metadata elements for describing electronic assets on the Web. We hoped that a relatively simple set of descriptors could be widely applied so the task of traversing silos of information would become easier on the Web than it has been in the physical world.

Dublin, Ohio, (OCLC’s headquarters, and location for the first workshop), gave us the name for the original set of 13 metadata elements—attributes of our document-like-objects that would help others locate and categorize them. We called this set of elements the “Dublin Core” or simply “DC” for short. Our objective, naïve in some respects, was to balance practicality and complexity, aiming for descriptions that untrained users might construct reliably, and which would make resources more findable. We created something that had some traction in the loose, fast-moving community of the early Web, something that attracted consensus from content specialists, Web technologists, and librarians. Bottom-up consensus building was, and remains, an essential attribute of what evolved into the Dublin Core Metadata Initiative (DCMI).

The name of the element set, in addition to reflecting its geographic patrimony, captures the notion that DC is a starting place (a core). It has always been an expectation that DC would be a kernel around which other metadata would grow. That first meeting generated basic principles that continue to guide DC development: Elements would be:

- Intrinsic (describe one thing)
- Extensible (modular, easily expanded)
- Syntax Independent (keep syntax and semantics separate)
- Optional (use only the elements you need)
- Repeatable (as many instances of a given attribute as appropriate)
- Modifiable (element “refinements” could be used to sharpen descriptions)

We wrote up the report,^[1] and published a synopsis in the first issue of *DLib Magazine*.^[2] Eric and I felt like we’d launched something of interest, but neither of us knew what to do next. We hoped a path would reveal itself, and in fact it did, in the person of Lorcan Dempsey, then leader of the United Kingdom Office of Library Networking (UKOLN) in Bath, United Kingdom.

THE WARWICK METADATA WORKSHOP^[3]

Lorcan suggested we might extend the reach of the original effort through a follow-on event in the United Kingdom. Thus did our one-off effort acquire a trajectory. The University of Warwick had a perfect conference venue for the sort of meeting we envisioned: good meeting rooms, all accommodations onsite, and a great bar that stayed open late.

Each of the early workshops had a tight-wire feel about it, a sense that what we were doing was fragile, and to emerge from a workshop without a major step forward would be fatal. The major result of the Warwick meeting was what came to be known as the “Warwick Framework,”^[4] a conceptual architecture for metadata that recognized the requirement for modular, extensible metadata. The ideas articulated in the Warwick Framework helped us decide what should be part of the Dublin Core and what might be borrowed from metadata element sets designed by others. The infrastructure scarcely existed to support deployment in those days, but the idea survived the intervening years of change, slowly morphing into what we today refer to as “application profiles”—hybrid schemas comprised of elements drawn from some number of metadata sets.^[5] These ideas hold up well in the current world of metadata, as long as the element sets can be declared within a common data model, a proviso that has been a sticking point for interoperability from the very beginning.

DC-3: OCLC–CNI WORKSHOP ON IMAGE DESCRIPTION^[6]

At this point in 1996, we still didn’t have a strong sense of where we were going. In fact the third “DC workshop” wasn’t chartered as such at all. It was co-sponsored by the Coalition for Networked Information (CNI), one of the last major efforts of Paul Evan Peters prior to his untimely death. Eric Miller did most of the organizational work, building on our experiences with the first two DC workshops. We didn’t announce it as part of the series, but the subtext of the meeting was basically: Can a simple DC element set be used effectively to describe images? The consensus of the group was yes, though there was a strong sense that the 13 elements needed to be augmented with two additions: “Rights” and “Description.” We declared,

somewhat belatedly, that this workshop was the third in the DC series.

The group felt fairly strongly that without the means to determine intellectual property rights (IPR) associated with an image, just finding it was inadequate. History tells us otherwise. The use of the “Rights” element remains marginal at best, largely because it is a difficult problem, with many infrastructural and legal dimensions that are not easily dealt with in a simple declarative metadata element. Nonetheless, it at least has provided for simple declarations about IPR, and a convenient hook for future deployment.

The “Description” element was brought into being because conferees felt that the “Subject” element did not encompass the notion of an image description sufficiently well, and that a separate element was necessary. One may argue such distinctions forever—I would probably resist this element more strongly today. It is easy enough to condense these two elements as “aboutness.” But DC was then, and continues, to be a consensus activity: a roughly-right solution that attracts usage is to be preferred over perfection that never arrives.

At this point it was clear we had a workshop series on our hands, and the acronym DCMI—Dublin Core Metadata Initiative—came into use. One memorable moment, which reinforced this sense of impact, came at a metadata interoperability workshop held near Bonn, Germany, late in 1996.^[7] I attended this small workshop to learn that a group in Osnabrück, Germany had launched a digital library effort that harvested metadata for mathematical preprints. Judith Plümer reported on work she and Roland Schwänzl had led using Dublin Core metadata. It was the first time I encountered people who had not been active in the DC effort, but had simply recognized it as something of use to them and deployed it. Roland later became an enthusiastic DCMI contributor until his death in 2004.

DC-4: SURFACING DOWN UNDER^[8]

We certainly thought of ourselves as working on a problem of international scope, and we wanted the venues of the workshop series to reflect that. Australia was actively shaping a government metadata standard based on Dublin Core. Renato Iannella, then of the Distributed Systems Technology Centre in Brisbane, Australia and Warwick Cathro, of the National Library of Australia in Canberra, had attended the Warwick Workshop (DC-2, if you will), and were enthusiastic about broadening the geographic scope of the effort. The National Library of Australia offered to host the meeting. We wondered how we could manage to get people (especially public sector people, who rarely benefit from international travel support) to attend. Australia is a long way from both Europe and the Americas. But it is the “World-Wide Web,” not the U.S. Web or the European Web, and we felt it was important to

reflect that global perspective in our efforts. This approach remains central to choosing locations for DC conferences, rotating venues among Europe, the Americas, and Asia.

We enlisted the support of the National Science Foundation, attracting small amounts of funding that we shared with applicants to help make their trips look (financially) more like domestic travel. No one got a free ride, but rather these funds helped to keep travel costs manageable. “DC-Down Under” helped consolidate the work that we’d done to date, and resulted, in part, in the first adoption of DC as a national information standard. This precedent continues today—adoption and localization. Australia was then, and continues to be, an important locale for the advancement of information description standards, and their hosting of DC-4 was a convincing testament to the international character of the effort.

Discussions at DC-4 raised the specter of “creeping elegance” within the community. We all want simple... but exactly the right degree of simple. The functional requirements differ from application to application and domain to domain. For the first time we tried to instantiate notions articulated in the Warwick Framework—modular and extensible metadata. The so-called “Canberra qualifiers” emerged—a first attempt to provide the extensibility that developers wanted to meet the local requirements in their applications. One may cavil about complexity and simplicity, and where the right balance lies, but that balance point is found in applications rather than theory.

Thus were element refinements born. We agreed that the basic fifteen “buckets” could be refined in order to sharpen the description. A date might be a date of publication, a date of copyright, a date of availability, or something else. It is permissible to refine or qualify the basic date field so as to make explicit the character of the instance.

But what if people use different refinements? The “dumb-down principle” emerged as (an unfortunately named) rule of thumb, decreeing that applications that lacked knowledge of a given refinement could simply ignore them. Some information may be lost, but the user will be no worse off than having had unrefined elements in the first place.

The “one to one principle” emerged in Canberra as well: in Erik Jul’s paraphrase of Ranganathan: “to each resource, its [own] description.” Why is this not obvious? Once again, the tension between alluring simplicity and tempting complexity arises. In the ideal world, all descriptions should be as discrete as their referents. “Stuart Weibel” is the author of this history, but his email address has nothing more than an accidental relationship to it. Still, I might want to have it in the document. Is it metadata? About what? Certainly not the document, though readers may find it handy to have it. It is metadata (contact information) pertaining to a “person,” not an “information asset.” “One to one,” then, is a many-headed-snake, and it has bitten us often over the years.

There was one other advance at DC-4: the workshop T-shirt. Lynn Marko, of the University of Michigan, arrived with her husband, Ken, then of Ford Motor Company. Unfortunately, Ken's luggage didn't make it. We gave him a couple of T-shirts to tide him over. Ken repaid the kindness many times, sponsoring several future workshop T-shirts.

DATA MODELS: WHENCE THE DEVIL RESIDES

While it is useful to recount DCMI history in the rhythm of its annual workshops, a good deal of activity took place outside as well. Workshops begat working groups, tasked with specific objectives, and laden with sunset provisions (working groups were chartered with specific objectives and expired at the following conference). Among the most difficult of objectives was the evolution of a data model for the Dublin Core. No experience of my professional life has been as contentious as these meetings. They were so singularly disruptive that we changed the names of the working groups to protect the guilty and innocent alike. Initially we had a Data Model group, and later an Architecture group, and the name of the outcome evolved from data model to abstract model. (More on this topic follows).

The early DC workshops were about broad consensus, and they were fiery experiences. Those early "bun fights" revealed a pattern of rising expectations, followed by a rapid slide into a trough of contentious argumentation before we "bounced" to find a plateau of consensus that moved us forward. In Canberra we had to push beyond the surface of simple descriptive metadata to the rather more complicated underpinnings necessary to achieve interoperable metadata systems. This realization paralleled similar recognition elsewhere in the Web. Protocols were evolving, new standards, both formal and informal, were emerging. DC at this stage was far from a standard, but certainly there was recognition that it needed to be if it were to take root.

Somewhere in this interval, Bill Arms, then of the Coalition for National Research Initiatives (CNRI), arranged a meeting that would help jumpstart the formulation of the Resource Description Framework (RDF) working group at the World Wide Web Consortium (W3C). Political pressure to support filtering of content so as to avoid the inadvertent exposure of minors to pornography had led to something called PICS (Platform for Internet Content Selection). PICS was a bit of *ad hocery* born of expedience without great forethought, and did little but provide a sense that someone was at least working on the problem. Recognizing that PICS was a rather-too-specialized solution, W3C folks had it in mind to generalize it as a platform for formalized semantics—metadata. Tim Berners-Lee is credited with originating the notion of the Semantic Web, and RDF would become a key enabling technology to support it.

Jim Miller, then of the W3C, Dan Connolly, also and still of the W3C, Bill Arms, and myself met to discuss the idea of an open community working group to address the issue. I was there largely as a prospective consumer of the results (that is, as leader of a community that could both use such a technology and provide practical functional requirements). Thus began DCMI's tightly coupled relationship to the beginnings of the Semantic Web. Key DCMI participants have been intimately involved in Semantic Web activities in the W3C and the wider community since that time. Indeed, my colleague at OCLC, Eric Miller, would eventually move to the W3C and become the Semantic Web Lead.

THE UNFINISHED CACOPHONY: DC-5—HELSINKI AND THE FINNISH FINISH^[9]

Early DC workshops were hosted by the players: the organizations and people with a stake in the effort. Juha Hakala of the National Library of Finland stepped to the line for DC-5, hosting the meeting in Helsinki. We stayed in a wonderful hotel on the waterfront, within easy striking distance of the herring boats and an urban architecture evocative of Tolstoy.

Resource Description Framework (RDF) was a hot topic in Helsinki, held high by some participants as the answer to the infrastructure impediments holding back metadata applications. Others grumbled, eyes narrowed with skepticism, concerned that RDF was immature and over-hyped. But everyone was eager to find solutions, and knots of conferees could be found huddled over laptops in the lobby at 2 A.M or with laptops open on restaurant tables sorting through problems of syntax and semantics. The stamina, good will, and collective work done at these workshops remain for me the epitome of professional dedication, as well as foundations of lifelong friendships.

As for elements and refinements, our slogan was the "Finnish finish. . ." the equivalent of the "Mission Accomplished" banner on the aircraft carrier of metadata. While it is true that no elements have been added since DC-2, and a number of element qualifiers were in use, there were yet plenty of arguments to be heard.

Among the DC geezers, people still talk of the tar ice cream served at the conference dinner in Helsinki. . . a crystalline, ice-white concoction that, paradoxically, evoked tar and freshness at once. The flavor of pine tar and peppered strawberries defines my memory of this great northern city. The T-shirt was great, too. . . we had a Dublin Core World Tour T-shirt with the element set in three languages on one side, and the stops and dates of the global tour on the other. The listing embodied at least three variant syntaxes for dates, and some of us imagined mischievous intent in Juha's grin. T-shirts, and now, too, a song. The workshop came to a close with a group sing-along, a characterization of workshop achievements

superior in brevity and eloquence to the workshop report. I confess having been taken somewhat aback at this development. At a followup meeting soon after, I asked Roland Schwänzl, our German Mathematician-cum-metadata wonk. . . “Is this sort of thing common in Europe. . . a song of summary after a workshop?” Roland seemed surprised at my question. . . “Ja Ja!”

GROWING PAINS AND CONSOLIDATION: DC-6 (DC:DC)^[10]

Our premature declaration of success from Helsinki was not long un-tattered. The DC Tour traveled next to the Library of Congress in Washington, D.C. The meeting included representatives of the INDECS project (a metadata activity focused on rights declarations), who felt we’d gotten a few things wrong. Of course, we had. The tension between INDECS and DC is classically a top-down/bottom-up conflict. DC evolved by consensus and the judgment of practitioners, INDECS by deductive inference. Each model has strengths, and each has weaknesses. To quote Marshall Rose:

The distance between theory and practice is always smaller in theory, than in practice.

We had hopes of finding the means to bring the two efforts closer together, and I think both activities would have benefited. DC and INDECS supporters collaborated on a paper in an effort to promote this convergence,^[11] but in the long run our differences were too great. One proposal motivated in part by this hope of consolidation, and in part by an ongoing recognition that simplification of the set would be a benefit in the long run, became known as the “secret agent proposal.” The notion of consolidating Publisher, Contributor, and Creator into a single element (“Agent,” or “Names” perhaps) was floated quietly among some DC participants. The idea never got to the point of serious open consideration, as there was strong opposition based on breaking legacy applications. This was perhaps the first time we were aware that DC *was* a legacy system. We weren’t engaging in an intellectual exercise in resource description: people cared, and systems depended on stability. The outcome of this attempt at reconciliation was almost certainly impaired as well by a sense of hostile intent between the two camps. This was, I believe, an unfortunate interpretation of the very natural inclination to cling to one’s own ideas. The clarity of hindsight leaves me with regret that we did not accomplish this simplification of model and application.

In this same vein, the RDF proponents lobbied hard to make this syntax the preferred encoding of DC metadata instances. There was strong pushback by others, who judged that simpler encodings (embedded HTML meta-tags for example) were being deprecated in favor of what

they judged to be an over-elaborated and unproven technology that mere mortals found hard to grasp. The practitioners reined in the wild-eyed theoreticians with a “Now just hold on!” Those of us who believed in the value of RDF (I count myself among them) had to acknowledge that we weren’t marching inexorably toward a single, coherent deployment strategy, but that various paths would persist, progressing at their own speeds, indefinitely. DCMI needed to support each of these paths. It still does.

Hindsight may be 20/20 vision, but I am still blind on this one. On the one hand, a single deployment path would have greatly simplified the onerous task of syntax support, and consolidated more effort around reference code. This would have been helpful (still would be, for all that). On the other hand, the Web teaches us that technology deployment in the early twenty-first century is riverine and decentralized. Attempts to channel and coerce are rarely successful. As I write this, nearly a decade later, RDF struggles on, seemingly gaining momentum, but the tools and techniques we expected to catch fire have mostly smoldered. Timing is everything, and we may have been ahead of the curve, or perhaps off in the weeds. The last chapters are yet unwritten.

The conference dinner for DC:DC was held in what was once the library for the Smithsonian Institution—a large and lovely hall in the Smithsonian’s “castle,” its first building. On the way into the dinner, there were Buddhist monks engaged in the composition of a sand Mandela. These meticulously wrought sand paintings take many hours on the part of several monks, and at the end, the visual esthetic, created as an act of prayer, is swept away. Standards creation is a bit like this, a kind of hopefulness that is inevitably short lived, but may nonetheless result in an abstraction of intent that reverberates in many ways through its practitioners and community.

That dinner was a great one, and fomented another workshop sing-along. I do not know all the details of its genesis, but I am given to understand that Diann Rusch-Feja and Godfrey Rust of the INDECS project were co-conspirators. The lyrics, sung to the tune of “Both Sides Now,” were, as in Helsinki, a far more succinct summary of the workshop than any reports could have captured. I hope someone still has the lyrics.

THE BIG VOTE

The instability of consensus regarding qualifiers led to a formal voting procedure in 2000 that marked an inflection point for DCMI, creating for the first time a structured (if yet messy) procedure for decision-making. We subsequently borrowed governance methods where we could find them—the Internet Engineering Task Force (IETF), MARBI (the community that looks after the MARC standards), the W3C, and others. From these, we crafted

procedures to make evident a commitment to open, public processes to manage the element sets in our care.

The DC Advisory Committee, made up of working group chairs and invited experts, agreed to vote on proposed qualifiers. The results of this vote comprised the first formal approval of terms beyond the basic 15, and what we learned in the process informed the next stage of formal procedures, which remain largely intact today. This vote, contentious though it was in certain respects, marks the maturing of the Dublin Core from a group of metadata enthusiasts to a formal standards community. The character of the meetings changed at about this time as well, evolving away from contentious passions to a more business-like collegiality.

DC-7 FRANKFURT

Die Deutsche Bibliothek hosted the next workshop in their splendid facility in Frankfurt, Germany in 1999. The tenor and scope of the workshops evolved towards a stronger educational and informational tone, leaving behind us the sense of “we’ll-die-if-we-fail” and strengthening the recognition that DC had a strong foothold that wasn’t going to evaporate. There were, of course, myriad details of contention and ambiguity that required attention. But the approach was workman-like and deliberate, with a confidence born of more stable ground beneath our feet.

DC-8, OTTAWA, AND LOM^[12]

The following year we returned to North America for DC-8 at the National Library of Canada in Ottawa. One of the important developments that emerged at this meeting was a closer alignment between the Learning Object Metadata (LOM) community and the DC community. LOM embraces both descriptive metadata for resources, based on Dublin Core semantics, as well as a variety of other classes of metadata intended to support management and use of educational resources.

Unfortunately, the two initiatives evolved in different directions structurally, a problem that plagues the technical implementation of metadata to this day. In Ottawa, DCMI and LOM agreed on a Memorandum of Understanding that has helped to guide a slow process of convergence. One of the deliverables of that agreement remains an important articulation of common principles that should be useful to many communities: “Metadata Principles and Practicalities,” co-a by principals of both initiatives.^[13]

The enduring lesson of the long history between DCMI and LOM is that without a common underlying data model, sharing metadata becomes difficult, imprecise, and (perhaps most crippling) expensive. I’ve drawn

an analogy elsewhere to the incompatibilities between railway gages.^[14] Different underlying rail gages force the unpacking and reloading of cargo, whether bales of cotton or metadata. The lack of a common underlying metadata model remains, in my estimation, a major impediment to broad cross-disciplinary metadata interoperability.

DCMI COMES OF AGE

In 2001, the DCMI community transitioned from workshops to conferences. In addition to the working group meetings, we offered a tutorial track and a refereed conference paper track. The National Institute for Information (NII) in Tokyo hosted the meeting in their beautiful facility a short walk from the Imperial Palace. We marked this transition in the names of the conferences, using years to distinguish them. The transition from a standards creation activity to a standards maintenance activity was taking place as well, and much more of the effort involved sharing of practice, through tutorials, plenary lectures, conference papers, and poster sessions. The locations of the conferences, listed in Table 1, are testament to the ongoing commitment of DCMI to its international foundations.

Behind the public face of the Initiative, much work was still underway to strengthen the procedures necessary to support an evolving standard. We reorganized the structure and procedures of the initiative, to include:

- A Board of Trustees: distinguished representatives of sectors and regions with experience and commitment to the advancement of the Dublin Core, and metadata in general.
- The DCMI Directorate: administrative staff to manage the activities of the Initiative.
- A Usage Board: recognized experts in the field who would review and guide proposed additions or changes in the standard.
- An Affiliate Program: Institutional sponsors for DCMI in various countries around the world to promote and support DCMI activities.
- An Advisory Board: (successor to the original Advisory Committee) Working group chairs that have been involved in the evolution of DCMI and other invited experts who provide consultation and advice.

Table 1 The Dublin core conference series.

DC-2001	Tokyo, Japan
DC-2002	Florence, Italy
DC-2003	Seattle, WA, United States
DC-2004	Shanghai, China
DC-2005	Madrid, Spain
DC-2006	Colima, Mexico
DC-2007	Singapore
DC-2008	Berlin, Germany

Building an organizational structure for the initiative also exposed issues of ownership and sponsorship. OCLC generously paid most of DCMI's bills for more than the first decade of its evolution, but certainly never owned or directed its development. OCLC's role as host was a side effect of the organizational involvement of myself and Eric Miller and the willingness of OCLC management to support our efforts. Subsequently, the formal link between OCLC and DCMI has been (amicably) severed, DCMI having been established as a limited liability company under the auspices of the National Library of Singapore; DCMI's formal organizational structure now reflects what was always operationally true—a genuine operational independence befitting a community-based initiative.

As the need for managerial capacity evolved, Makx Dekkers and Tom Baker were enlisted as members of the DCMI Directorate. Tom had been an active contributor to DC since the second workshop, and has authored many papers and DCMI documents that are milestones of DC development. His knowledge of languages and linguistics have been particularly valuable. I have been privileged to have shared with him many wonderful brainstorming sessions about metadata. Two particularly memorable experiences—developing notions of metadata grammar atop a sunlit tower in Lucca, overlooking the Tuscan hills, and a middle of the night Japanese “onsen” (hot springs bath)—rank among the most pleasurable of work experiences. Makx, also a long time DC participant, brought to the initiative strong project managerial skills and experiences in the European standards world.

My own role in the Dublin Core began to decline during this period. Start-up and sustenance require different skill sets. Separating from guidance and management of DCMI was both difficult and right (for the Initiative and for myself). But surely surviving its founders is an important measure of success for any organization!

STANDARDIZATION STRATEGIES

For most countries and many large organizations, information management practices must be built around formal standards. Our approach was to transition DC from simpler to more formal efforts. We started with an IETF RFC (request for comments). The IETF route had two advantages: many of our anticipated adopters came from the Internet culture, and establishing an RFC was relatively simple. An informational RFC is little more than a public declaration of an approach, useful for informing others of what has been done and why it is the right thing to do. It requires a minimum of external review or persuasion. Publication of RFC 2413 in 1998^[15] constituted the initial stake in the ground for standardization of DC metadata (this RFC was updated as RFC 5013 in 2007^[16]).

Subsequently DCMI embarked upon standardization in the National Information Standards Organization (NISO)

in the United States. NISO approval was seen as a step to international standardization in ISO, as NISO is a U.S. organizational member of ISO. NISO standardization proved challenging, both because DCMI encountered political opposition in various quarters, and because we were the initial use case for a “fast-track” approval process intended to reduce the latency of standardization activities in a rapidly changing Web environment. Pat Harris, then director of NISO, skillfully negotiated the minefields, and helped DCMI achieve this important imprimatur, and DC metadata was standardized as ANSI/NISO Z39.85 in 2001. Once DC metadata became a NISO standard, ratification as ISO 15836 followed relatively easily.

THE DCMI ABSTRACT MODEL AND INTEROPERABILITY

As alluded to earlier, data modeling has from the start been problematic for DCMI. In pre-Web days, it was less important to have a formal model for metadata. MARC standards, for example, have never benefited from an underlying data model, and yet have enjoyed wide adoption and usefulness. As infrastructural boundaries between domains have dissolved in the universal solvent of Web protocols, the need for agreements about syntax and structure increased. While humans readily distinguish nuances of meaning and structure, machines do not.

The formal emergence of a data model for DC took a decade. The final breakthrough was spearheaded by Andy Powell and Mikael Nilsson, following on Tom Baker's exposition of DC grammar^[17] (and a decade of vociferous argumentation from many quarters). The DCMI Abstract Model (DCAM)^[18] abstracts the basic metadata entities used in DC metadata and specifies their expression in RDF.

Sharing metadata requires agreements on a variety of levels. Some of the salient issues:

- What is the meaning conveyed in metadata assertions? Meaning, of course, resides in the minds of people, not machines. The focus of the Dublin Core was initially on promoting common meanings and making them sharable on the Web.
- How are metadata assertions packed so that one machine can send them to another without changing their meaning?
- How can metadata be structured so as to assure consistent and unambiguous interpretation? Reliable syntax encoding requires consistent data structures. The sorts of things that must be specified in a well-structured metadata assertion include:
 - The boundaries of a set of assertions (what constitutes a record)
 - Cardinality: can an element be repeated, and if so, is there a limit on the number of repetitions?

- How is a name structured? What is the delimiter separating elements of a compound name (“Prince” and “Bono” excepted, most names are compound structures, many with surprising and confounding complexity).
- At what granularity are descriptions associated with resources? How is nesting managed for hierarchical resources?
- How are dates encoded? YYYY-MM-DD? DD-MM-YYYY? MM-DD-YYYY?
- How does one identify an encoding scheme that specifies the above question?
- How are character encodings declared?
- How does one identify a value-encoding scheme (e.g., LCSH, MeSH, Dewey...) from which metadata values can be chosen? Are such schemes required or optional?
- Are metadata values specified by reference (URI) or by value (literal strings)?

It is in these details that the success or failure of interoperability is written; understanding and declaration of these details remains incomplete.

Current thinking among DCMI metadata architects suggests it is useful to distinguish four levels of interoperability, each characterized by a set of choices, costs, and benefits:^[19]

Level 1: Informal interoperability: A vocabulary of concepts expressed in natural languages that support sharing of meaning among people. Metadata terms can be described as informally interoperable with Dublin Core if their natural language representations can be mapped to the 15 legacy DC elements. There is no requirement for DCAM conformance, and values for metadata are expressed as human-readable strings. Prospects for machine-to-machine interoperability at this level are low.

Level 2: Semantic interoperability: Metadata that can be accurately and completely expressed using RDF formalisms, but which is not conformant with additional structures elaborated in the DCAM.

Level 3: Syntactic interoperability based on the DCMI abstract model: RDF-compatible metadata that conforms to all elements of the DCAM (in particular, “bounded descriptions”—a collection of metadata assertions bound together and identified as what is thought of as a “record” in traditional bibliographic practice).

Level 4: Singapore Framework Interoperability: Conformance to a complete specification of functional requirements, a domain model, and description set profile.^[20]

Levels 1 and 2 roughly define the divide between human-sharable and machine-processable metadata strategies of

the first decade of DC’s existence. Level 3 promises a higher level of interoperability through conformance to abstract metadata structures that are defined in the DCAM (in particular, bounded records which can be identified using URIs). The benefits of these additional structures accrue to managing and validating metadata collections.

If Level 4 seems vague, it is perhaps a reflection of yet-poorly understood requirements for bringing together large aggregations of heterogeneously managed metadata collections. This remains an area of active exploration.

At this writing, metadata modeling experts do not agree on the finality of the DCAM, or its general usefulness for all metadata. It is currently the closest approximation of a generalized data model for metadata in a Web environment, and is one of the most important contributions of the Dublin Core to the larger metadata community, the result of many years of grappling with a difficult problem.

SUMMARY

The protocols and standards that underpin our digital lives are, in the long term, as ephemeral as the sand mandalas of the monks. The understanding that emerges from their creation, however, is part of a more persistent trajectory. The Dublin Core marks its 15th year in 2009, arising and co-evolving with the Web itself. The conference series remains the preeminent venue for defining and deploying structured description on the Web. Its practitioners are found in 50 or more countries, and its descriptions are quietly at work in applications that serve literally billions of people over a range of domains that includes the latest media formats, government publications, scientific data, Internet syndication feeds, image collections, and many more.

The architecture and details of DCMI metadata have evolved over its lifetime. Its practitioners have labored together in meetings in 30 countries or more. Notable venues for DC events include the rolling hills of Kataminga, outside Melbourne, Australia (the first DC-Education meeting), the magnificent National Museum of Art in Canada (DC-8 conference dinner, Ottawa), the splendid conference hall in the National Institute for Information in Tokyo (DC-2001), the Shanghai Library (DC-2004) and perhaps most spectacular of all, the Hall of the 500 in the Palazzo Vecchio in Florence (DC-2002 conference dinner). The privilege of working and socializing in such places (and so many others, too numerous to mention), have left rich imprints on participants and the work alike.

The principles and practices elaborated in DCMI reverberate throughout the metadata community and provide a useful framework for metadata now and into the future. That this is so is a credit to the many people who have contributed their time, their expertise, and their passion to its evolution. These efforts are an important and lasting contribution to the digital future.

Economics Literature: History [ELIS Classic]

Arthur H. Cole

Laurence J. Kipp

Harvard University, Cambridge, Massachusetts, U.S.A.

Abstract

One of the objectives of the information disciplines is to study the universe of recorded information—that is, to study the documentary products of domains of human activity—and to come to understand such bodies of literature as social and historical phenomena in and of themselves. Cole and Kipp describe the development of the literature—including periodicals—of economics from the Renaissance to the twentieth century. The development of economic theory and understanding is discussed in relation to the development of the literature of the field.

—*ELIS Classic*, from 1972

INTRODUCTION

This survey aims to consider the printed materials dealing with economic and business activities in Western Europe and the United States, with some reference to publications emanating elsewhere. It seems appropriate to handle all economic and business printed literature as a single whole, for when the entirety of this literature is examined, one finds no clearly marked dividing lines. All items can be regarded as falling in a spectrum, extending perhaps from a mathematical formulation of international trade to a flyer in Canadian uranium stocks. The differences are notable at the extremes, but there are no sharp breaks in the succession of types.

Nearly all economic and business literature is purposeful, intended by its authors to be of use in modifying public policies, improving business performance, informing the youth or the general public, and providing other than amusement or aesthetic enjoyment. This review of economic and business literature, therefore, seeks to determine how it has served its purposes. It is also necessary to determine whether the materials for the formation of public policies has changed over the centuries. If so, how and when? More in some countries than in others? It is also pertinent to inquire whether economic theorizing has improved over the centuries, i.e., can economists be said now to think better than those of 100 or of 200 years ago? And do economist and businessmen think differently from their predecessors of 1850 or 1750? If so, in what ways? and as result of what forces?

Concepts are slippery things and seem often to have gotten into the literature only with difficulty. This study of economic and business literature, therefore, attempts to reflect the process and the timing whereby and when concepts important in this area were introduced into printed form, repeated in other printed items, and incorporated

into libraries where the policy makers or the research members of their staffs could gain access to them and use them.

The centuries since Gutenberg seem divisible, as far as economic and business literature is concerned, into four periods of somewhat variant length—one lasting until the latter half of the seventeenth century, another extending thence until the closing years of the eighteenth, a third from then until about 1880, and a fourth extending to the present. These are set off by more than one phenomenon in all cases, and the dividing dates become rather fuzzy. However, the periods have distinctive characteristics.

HISTORY

The First Period

The first period was one of mixed movements, extending from the invention of printing with movable type to the latter decades of the seventeenth century. Within it, there was an extension of themes from preprinting days; there were new themes that failed to persist, as if lacking in pertinence; and there were other new themes that gained the strength to spill over into subsequent periods.

The publications of the earlier portion of this period, and to some extent throughout it, reflect considerations or controversies of pre-Gutenberg days. There were the treatises and tracts pertaining to usury and incunabula, such as the booklet by Consobrinus, and as late as 1634 John Braxton's *Usury Condemned*. Books on agriculture also kept appearing all through these centuries—and of course have never ceased appearing. The classical writers on agriculture were frequently reprinted in the early decades of printing: *Scriptores Rei Rusticae*, among the incunabula; the collection called *Geoponica* somewhat later; plus

individual Latin authors, often also in translation, rather thickly down through the middle of the sixteenth century. Overlapping with them and continuing later were the books by such authors as Estienne, Heresbach, Markham, and Tusser.

There was a third type of continuing item: compilations and treatises upon commercial law. They appear in the fifteenth century and continue like the books on agriculture. In some measure there was change here over time. For example, the “Consulate of the Sea” type of compilation reaches back into pre-Gutenberg days, but they became infrequent after about the middle of the sixteenth century. And then there is the case of Malynes. His *Consuetudo, vel, Lex Mercatoria*, the leading English specimen of its genus, first published in 1622, went through a growth that seems to mirror the changing business world. By 1656, appendices had been added in which the exchange of money by bills was “anatomized,” and the “ordering and keeping” of merchants’ accounts were explained. Knowledge of the law was apparently moving over to give place to knowledge of business practices.

In these decades, there were some literary occurrences that stirred no immediate continuing developments. One is the Malynes-Misselden debate over the effects of the exchange rates. Their contentious pamphlets flew back and forth in the early 1620s and then everyone appears to have forgotten about the matter. There was a considerable number of items pertaining to money in the sixteenth century, including Jean Bodin’s famous *Apologie*, but then little was published again until the eighteenth century. Finally, one may note the tracts of the Levellers, especially Gerrard Winstanley, in the Commonwealth period, expounding communistic ideas that were not to become common for another couple of centuries.

On the other hand, some novel developments may be recorded. One is the rise of the controversial pamphlet related to secular affairs. This was something new in the world. The outpouring was much the greatest in England. The names of Sir Dudley Digges, Thomas Mun, and many others will occur to students of the history of economic thought. There were some comparable items of Continental origin, such as those of Laffemas in France or of Pieter de la Court in Holland. On the whole, however, the Continent remained an inhospitable area for publications of this type, even to the end of our next time period, the close of the eighteenth century, except for the Netherlands and Sweden. With all due allowance for these countries, England provided the richest and most productive soil for this form of literature.

The period also brings the first calls to make money. The oldest book on retail selling, William Scott’s *Essay of Drapery* (1635) seems to take a stand with one foot in the Middle Ages and one in the modern world. As early as 1558, Roger Bieston had been willing to argue that money was “a necessary mean to mayntayne a vertuous quiet lyfe” in his *Bayte and Snare of Fortune*. Gervase Markham

thought it advantageous—presumably in keeping with the spirit of the times—to label a book on agriculture practices *A Way to Get Wealth* in 1625. So uninhibited had the sponsors of wealth seeking become by 1684 that a volume with the gay title of *The Pleasant Art of Money Catching* could be published.

There were also the first publications of types that have since blossomed luxuriantly. One may note two subvarieties of manuals: one with a geographical and another with a technical base. The former type existed as early as the fourteenth century. There were specialized printed specimens devoted to the moneys of various regions, appearing as early as 1530 in Antwerp, and in Vienna in 1563 (which had progressed to being a reckoning book). Books of broader coverage were soon to be issued: one in 1576 out of London, which gave data on “the most famous cities in Europe,” their “trade and traficke,” “their coynes and the places of their mynts,” to be followed half a century later (1638) by Lewes Roberts’ famous *Merchants Mappe of Commerce*. This extensive folio manual went through at least four editions, the last appearing in 1700.

The other subvariety includes books of arithmetic and ready reckoning, compounded particularly for the use of merchants, the expositions of bookkeeping such as Ympyn’s *Nieuwe Instructie* published in Antwerp in 1543, together with volumes of applied science, which may perhaps be considered to begin with Schopper’s illustrated book on mechanical arts, printed in Frankfurt in 1574.

A second general type of literature with a modern flavor is that stimulated or issued by individual companies. John Wheeler wrote his *Treatise of Commerce* (1601) in support of the Company of Merchant Adventurers; Sir Dudley Digges addressed his *Defence of Trade* (1615) to the governor of the East India Company; and Thomas Mun composed his *Discourse of Trade* (1621) in defense of that Company. Before 1680, quite a flock of pamphlets had been printed about enterprises from the “West-Indische Compaignie” of Holland to the “Company of Royal Adventurers of England Trading into Africa.” Sometime in the 1650s, if not indeed earlier, such enterprises commenced to issue material on their own initiative, e.g., *The Advantages of the Kingdome of England* from the operations of the “Fellowship of the Merchant’s-Adventurers of England” (c. 1650), which looks very much like a “public relations” piece or minutes of meetings of the general court of the English East India Company.

Despite these new sorts of items and despite the issue and reissue of divers books on agriculture, the general impression of the literature of this whole period is that of discontinuity and some naivete.

The Second Period

The second period was characterized by enhanced continuity, by the beginnings of measurement, and by the

development of integration—a period extending from the late seventeenth to the late eighteenth century.

The “continuity” is evident on various sides. The effort of the Parisian Académie des Sciences to prepare and issue its *Description des arts et métiers* is a case in point. The original idea was broached as early as the 1660s, it recurred fitfully in the next few decades, a more formal start was made in the 1730s, and the volumes appeared from the 1760s to 1788. The successive editions of Savary’s *Parfait négociant* from 1675 to 1763, of Ricard’s *Traité générale de commerce* from 1706 to a fifth edition in 1732, or of Thomas Mortimer’s *Every Man His Own Broker*, first published in 1761 and reaching its twelfth edition in 1798, yield the same picture—there was a persistent interest in the particular line of thought. Publishing houses were increasing within the economic and business field.

However, institutional connection was not essential. Continuity begins now to be more clearly apparent in the evolution of economic thought. Some such condition is evident in English mercantilist thought, especially after Mun; but it takes a more creative turn on the Continent. In France, there was the development of speculative ideas in Boisguilbert, Cantillon, Quesnay, and Dupont de Nemours, resulting in the advent of an informal group that promoted discussions and supported journals of communications. In Germany, one can find a persistent growth of cameralistic thought, beginning actually a little earlier than physiocratic ideas or preliminary notions, namely, with the publication of Becher’s *Politische Discurs* in 1668. Here, evolution took the road leading into administration and education. Officials of Austria and the German states were intimately connected with the development. And Hermann Conring (1606–1681), Gottfried Achenwall (1719–1772), and many other professors gave lectures that by and large were presentations of economic data relevant to public administration. This concentration of economic thought, teaching, and governmental activity persisted into the nineteenth century.

Continuity in the area of business communication presents a curious but intriguing picture. During the seventeenth and eighteenth centuries, merchants dominated the business communities of all countries; and merchants have always been interested in changes in commodity prices, movements of ships, and alterations in the course of exchange rates in about that order of declining values. A natural evolution in instrumentalities, once the volume and diversity of business required more than the partial picture conveyed by private letters from agents and correspondents, was that an entrepreneur would set up a reporting agency to serve a given community. Thus began *Oram’s New York Price Current and Marine Register* (1798–1804) and *Ming’s New York Price Current* (1805–1813, 1815–1817), which would be displaced in time by a newspaper of broader coverage—in this New York case, by the *Shipping and Commercial List and New York Price Current*, which in fact ran continuously (with only one

minor change in title) from 1815 to 1861.^[1] At other places, a mercantile journal carried current commodity price quotations as a regular portion of its news; this “prices current” section was reprinted on a flyer, sometimes with a merchant’s name added as a running head, and merchants distributed copies of these prices—currents to their correspondents.

Neither of these sequences occurred in the Netherlands and in England. In the one case, printed lists of commodity prices began to appear in the first years of the seventeenth century. They were soon compiled under regulations of the city and may have been printed by various booksellers for distribution. They continued to be issued up into the first part of the nineteenth century, and no general commercial journal seems to have blossomed on this stem. In the case of England, supposedly the “land of shopkeepers,” the story is one of unexpected deficiencies. Some privately printed merchants’ price lists appeared in 1670 and thereafter, but only intermittently until the first decades of the succeeding century. The only periodical that carried such price data seems to have been John Houghton’s *Collection of Letters for the Improvement of Husbandry and Trade*, which ran from 1692 till 1703. For 30 years or so after 1715, there appears to have been no public or semipublic commodity price reporting; then perhaps some specializing sheets; and not until 1775 and the launching of Prince’s *London Price-Current* can one grasp commodity price reporting that persisted into modern times in some form, if under various aspects.^[2]

In the meantime, to be sure, there had come periodicals that reported on financial affairs and on shipping: the semiweekly called *The Course of the Exchange* begun by John Castaing at almost the peak of the South Sea speculation, specifically in 1719, but carried on by him and his successors continuously ever since; and *Lloyd’s List*, which, starting in 1734, gave news of ship movements, share prices, and some general matters of commerce.

The eighteenth century has been referred to as the “era of political arithmetic,” and surely measurement became a more widely recognized desideratum. Doubtless, Sir William Petty should be canonized as the patron saint of modern economics. Writing of his “Method,” he stated that, “instead of using only comparative and superlative Words, and intellectual Arguments,” he had taken the course of expressing himself “in terms of Number, Weight, or Measure.” It is the creative ideas that are important: that in economic affairs, one might emulate the practices of the natural scientist; and from measurements one might derive apparent uniformities in economic life. Already John Graunt had seized upon London’s “bills of mortality”—perhaps the only good result of the plague—and had laid the first bricks in demographic studies and actuarial science. Graunt was followed by Halley, de Moivre, Price, and a continuing band of students and writers in England; and by an equally notable, if not really superior chain of successors on the Continent.

Other seventeenth and eighteenth century English writers in various fields of economics adopted the Petty approach. Arthur Young wrote a *Political Arithmetic* of his own, devoted largely to agricultural problems of his times. There was a new stress on “experience” and “experiments,” as in William Harte’s *Essays on Husbandry* (1764). In the meantime, too, the British government had seemingly become infected. Governmental reports began to be issued, often largely statistical in character, on the course of trade, the activities of the East India Company, public finance, and the like. These reports were generally irregular, but they laid the basis for the series that in 1801 began as the Parliamentary Papers.

In other countries, the zeal for measurement burned with variant brightness. In France, the impact appears not to have been great in this period though Vauban, Deparcieux, and few others were influenced. On the other hand, “political arithmetic” appears to have been quite congenial to cameralism. Johann Peter Süssmilch (1708–1767) became an exponent of the “method” in his own right. His *Göttliche Ordnung*, published in 1742, was noteworthy for its contributions to the study of what came to be called “vital statistics.” His contemporary, Gottfried Achenwall, was the first person to use the term “statistics.” Actually the word then signified general description of economic phenomena, not specifically quantified measurements and statement.

The notion of a census of population has been traced back to Bodin and Montchrétien. And certain censuses of population were taken in the eighteenth century: Sweden from the middle of the century onward; Austria in 1753, 1762, and 1777; not to mention certain Canadian provinces even in the seventeenth century. However, in Europe, population data were not broadly published until the nineteenth century; military rivalry was too severe.

The evolution of syntheses seems a third feature of this period. One aspect of this trend was the compilation of dictionaries or collections of information on various subjects—not merely merchants’ *vade mecums* such as Savary’s and Ricard’s but more specialized, topical affairs, such as the *London and Country Brewer* (1736), or Duhamel du Monceau’s six volumes on fishes and fishing (1769–1782). The Germans were particularly given to such compilations. Another type can be represented by *Select Essays on Husbandry* printed in Edinburgh in 1767 or John Almon’s *Collection of Tracts, on the Subjects of Taxing the British Colonies in America, and Regulating their Trade* published in 1773.

More noteworthy yet were the efforts of theorists Quesnay, Sir James Steuart, and particularly Adam Smith to describe or analyze economic systems. Professor Schumpeter speaks of “quasi-systems” in earlier times. By this Schumpeter seems to mean partial views of the whole economy, from which one may properly infer that their authors possessed quite surely a sound concept of the whole.^[3] There can be less doubt of the physiocrats, Steuart, and the “father of political economy.”

Smith’s *Wealth of Nations* illustrates the importance of conceptualization. It has been said of Smith’s book that, like the American Constitution, there is little that is original in it, and what is original isn’t very good. However, Schumpeter—curiously reluctant to see virtue in “A. Smith”—does assert:

We know that the skeleton of Smith’s analysis hails from the scholastics and the natural-law philosophers. . . . They had worked out all the elements of such a scheme, and Smith was no doubt equal to the task of co-ordinating them without further help from anyone.^[3]

The leading features of this period may be embraced under the general term “increased sophistication.” The developments of the decades after 1660 reveal a level of thought hitherto unattained in the economic and business field. Other phenomena lend support to this contention. One is the awakening of a historical sense, at least in this field of thought and publication.

The eighteenth century is noteworthy for the increase in number and the extension in variety of historical studies. Interest in coinage of the past was very early evoked (e.g., in Occo’s survey of Roman coins, published first in 1579). However, much more substantial works in this area were produced two centuries later (e.g., those of Leake and Snelling in England). And now appeared also such items as Madox’s *History and Antiquities of the Exchequer of the Kings of England* (1711), Raynal’s famous *Histoire philosophique et politique des établissements & du commerce des Européens dans les deux Indes* (1770), even such a piece of business history as Henning Calvör’s *Historische Nachricht von der Unter und Gesamten Ober Harzischen Bergwerke* (1765). Also not to be overlooked is the launching of effort in the area of price history—surely a “sophisticated” realm [e.g., Bishop Fleetwood’s innovating volume entitled *Chronicon Preciosum: or, An Account of English Money, the Price of Corn, and Other Commodities, for the Last 600 Years* (1707)].

Data of a somewhat different sort are supplied by the reprintings of earlier materials. Among those were John Smith’s *Chronicon Rusticum-Commerciale; or, Memoirs of Wool* (1747) and Robert Vansittart’s *Certain Ancient Tracts Concerning the Management of Landed Property Reprinted* (1767). The tracts were reproduced, not primarily because they would presumably be of utility in practical affairs, but seemingly because they were interesting in themselves; the wisdom of earlier times should not be forgotten, even if not immediately applicable to contemporary problems.

The increased sophistication, the rise of a historical sense, and the power of cameralistic thinking were responsible for another important development: the creation of bibliographies of economic literature. According to Kenneth E. Carpenter:

The first bibliography of economics was J. B. von Rohr's *Compendieuse Hausshaltungs Bibliothek* (first ed., 1716). For each of the subjects covered—"Cammeralwesen", agriculture, commerce, mining, etc.—Rohr provides a kind of encyclopedia article, with comments on books, which are in most of the languages of western Europe. Rohr disclaims any attempt at completeness, but as a classified bibliography, it is perhaps still useful for some purposes.

In his *Hausshaltungs Bibliothek*, Rohr added his voice to that of numerous advocates of university chairs of Cameralism. The first in Europe was founded at Halle in 1727, and others in Germany soon followed. It is probably to this early recognition of economics as an academic subject that we owe a long series of German bibliographies.^[4]

Carpenter identifies other bibliographies of the period:

Two unusual and very definitely usable items are J.J. Moser's *Bibliothec von Oeconomischen-Cameral-Policey-Handlungs-Manufactur-Mechanischen und Bergwercks Gesetzen, Schrifften und Kleinen Abhandlungen* (1758) and J.H.L. Bergius' *Cameralism Bibliothek* (1762). They are essentially indexes to periodicals and laws and can make available much detailed information.

These were published "prior to the work which has generally been considered the first bibliography of economic literature—the 34-page 'Catalogue d'une bibliothèque d'économie politique formée pour le travail du nouveau dictionnaire de commerce' in Mollet's *Prospectus d'un nouveau dictionnaire de commerce* (Paris, 1769)."^[4]

However, lest the element of sophistication be overemphasized, Professor Edwin F. Gay made a considerable reputation for himself by controverting statistically certain allegations of sixteenth century writers on the extent of the contemporary enclosures; and Professor Brebner has remarked that economic history writing of these centuries should generally be examined with much care; much of it was compounded to prove a case of some sort or another.

The use of earlier materials and of libraries was limited. One of the first notes about economic and business literature is contained in John Houghton's *Husbandry and Trade Improved* (1728).^[5] He lists what looks like 35 titles: something like 20 in Latin, of which 6 or 8 are reproductions of classical authors; 2 in Italian; 3 or 4 about trees; 2 or 3 about fishes; 1 about gardens; and More's *Utopia*.

It is recognized that the *Wealth of Nations* was not composed with a wealth of citations. It had not become the prevailing practice among scholars of Smith's time to acknowledge sources, but it is significant that in Smith's collection of books and pamphlets aggregating approximately 1600 items, there are scarcely 150 that could be labeled economic.^[6]

In the case of David Ricardo, there was apparently slight interest in predecessors. Despite Smith and Malthus and a few others, writers in the field were not generally learned.

Any impression that all proceeded smoothly in the evolution of economic and business literature is erroneous. Generally, the most advanced thinkers of given periods are taken to represent those decades. This, of course, is not a satisfactory procedure if one is interested in this literature as a vehicle of the formation of public opinion and public policy. Some attention to the irregularities or bulges from any trend line is justified. There was the Cromwellian period in England, with its enhancement of volume and its manifestation of new idea through its John Lilburne, Gerrard Winstanley, Henry Parker, Henry Robinson, Thomas Violet, William Potter, and others. There was also the peculiarly interesting period between Robert Murray's *Corporation Credit* (1682) and the early years of the next century. The volume of economic writing expanded now, especially in the 1690s, and particularly with the first sizeable crop of anonymous pamphlets, but it is also interesting how many writers of note from Nicholas Barbon to John Briscoe, and from Daniel Defoe to Sir Humphrey Mackworth fall into these decades.

In the meanwhile, cameralistic writings had flourished rather extraordinarily in greater Austria, if one may use that term. After Becher came his brother-in-law, Philipp Wilhelm von Hörnigk, with his *Oesterreich über Alles, wenn es nur will*, which went through 13 editions in the course of a century; Wilhelm von Schröder's *Fürstliche Schatz- und Rentkammer*, which enjoyed 6 editions between 1686 and 1752; and scores of lesser writers. There was also the especially interesting phenomenon of Paul Jacob Marperger (1656–1730). Perhaps he should be recorded as the first full-time economist; some 90 separate publications may be credited to him, running literally into thousands of pages. He did not really rise to the level of theory, yet Marperger did not publish trash. He represents at least a bulge from any general trend line, greater than that produced by Defoe, or earlier Samuel Hartlib or Gervase Markham.

A bulge of a different type centers in the South Sea and Mississippi Bubbles. This movement may be measured in the numbers of items recorded in the Kress Library printed catalog which lists 524 titles published in the years 1720 and 1721, compared with 128 in the years 1719 and 1722.

In Holland, this "bulge" seems to have flooded Amsterdam with scores of satirical prints. Several plays and several poems were also prepared relative to the speculation in shares. These and other documents pertaining to actual company ventures were gathered up and issued as a warning in a thick folio volume entitled *Het Groote Tafereel der Dwaashied* (or "The Great Mirror of Foolishness").

Similar deluges were to accompany later periods of excitement: the controversy of England with her colonies in America; in France, the problems of the new

government after 1789, especially those of currency, taxes, and the disposition of the lands of the Church and nobility; shortly thereafter in England and Ireland, the question of union between the two islands; and later still the “bullion controversy.”

The Third Period

The third period, from the late eighteenth to the late nineteenth century, was marked by the efflorescence of printed matter and by the very considerable spread of organization within the business world.

Professor Innis has posited a hypothesis that media of communication succeed one another as the arteries of business are lengthened geographically and the pulse of business quickens. Oral communication was feasible when merchants could make frequent journeys in promotion of their enterprises, although each journey might run into months. As a second stage, correspondents kept in touch with their principals by letter. This latter system must have been quite unsatisfactory and could not function adequately in such a trade as that which New York, Salem, and other American towns initiated with China after 1790.

The long period of wars between 1790 and 1815, with the uncertainties and changing demands that war always brings, seems to have stirred all segments of Western societies to cast aside the slow, private means of communication, to seek by political means an increase in the volume of governmental publication and to stimulate, by means of subscription payments to venturesome entrepreneurs, the expansion of commercial vehicles.

The British Parliamentary Papers began to be issued regularly in 1801; by the 1840s, 50 folio tomes were required, and by the 1880s, 90–100. The publication activity of the U.S. government kept close pace with that of the British. Regularity was imparted to the *Congressional Documents* only with the Fifteenth Congress (1819–1820), but many statistical and other materials were printed as individual *Documents* in the preceding 30 years.

In Canada, a documentary series of the Dominion began in 1841 and one of the province of Quebec in 1869. France and Germany have contented themselves with the publication of the reports of *Enquêtes* and *Ausschusses* and with that of special series, e.g., the French *Catalogue* and successive reports on inventions from 1791 onward or its *Tableaux généraux du commerce* in 1818 and later years.

A considerable proportion of this governmental activity may be attributed to the desire for measurement that arose in the late seventeenth century. The United States was a leader in statistical developments. The census of population of 1790 was the earliest to be published; in 1810 and 1820 the federal government made some effort to secure data on manufacturing facilities as well as population; and the reports on manufactures in the 1850, 1860, and 1880 censuses were more extensive than any elsewhere in the world.

Some of the American states became active in collecting data on population and in other lines: New York and Massachusetts, manufactures; Maine, ownership of bank stocks; and the like. There was the famous (if not too thorough) survey of manufactures and their likelihood of growth made by Hamilton, the better inquiry made by McLane in 1833, useful reports on various industries that accompanied the censuses of 1860, and 1880, and essays on such topics as coal measures or movement of tobacco accompanying that of the later date. The annual statistical reports, such as those on commerce and navigation (regularized in 1820), and some special reports such as that of I. DeW. Andrews on the commerce of the Great Lakes, or on internal commerce of the country (1876–1891), produced notably useful data.

Quantitative reports also appeared in such periodicals as Niles's *Weekly Register*, *Hazard's Register of Pennsylvania*, *DeBow's Review*, and Hunt's *Merchants' Magazine*. Two other private statistical publications not seen duplicated in any other country for some decades appeared: Benton and Barry's *Statistical View of the Number of Sheep* [in northwestern United States]; *And an account of the Principal Woollen Manufacturies in said States* (1837); and the other is William H. Sumner's *Statistics of the Woollen Manufactories of the United States* (1845). But the major private efforts come a bit later with the quantitative reporting of the *Commercial and Financial Chronicle*, including its annual *Investors' Supplement* volume of many years after 1875, and *Poor's Manual of Railroads*, of which a historical volume appeared in 1860 and regular annual ones after 1868.

In Europe (probably with the exception of Germany over the last decade or two of the period), the developments were less pervasive and somewhat more scholarly. There were published censuses of population, as in England in 1802 (and later decades), Sweden 1811, etc., but no industrial or agricultural censuses. Europe's principal contributions fell elsewhere.

“Statistical” activity in the sense of descriptive economics there was, and especially noteworthy examples pertain to agriculture in the British Isles, perhaps attributable to the influence of Arthur Young. The agricultural surveys of English, Scottish, and Irish counties were made between 1790 and 1815 or thereabouts. Those related to the British countries were prepared under the auspices of the semiofficial Board of Agriculture and Internal Improvement, some of them composed by Arthur Young. They number nearly 90 and were published between 1793 and 1800. Another series ran to more than 60 volumes and appeared between 1804 and 1815. Between 1801 and 1812, the Royal Dublin Society published surveys of 21 Irish counties (three others being published later: 1824, 1832, and 1833) with the slightly variant titles of a “general view of the agriculture and manufactures” of a given county, or “statistical observations” of the same.

More important was another contribution, namely, what Funkhouser describes as “the gradual merging of political arithmetic and the theory of probabilities in the science of statistics.” Funkhouser traces the evolution of probability theory back to Pascal and Fermat working in the middle of the seventeenth century and notes that de Moivre discovered the formula for the normal probability curve in 1733, that J.B.J. Fourier drew the curve in 1821, and that de Morgan first made published use of the curve in 1838.^[7]

There was a third contribution from Europe: new organizations in the field of statistics. The Statistischer Verein for the Kingdom of Saxony began publishing in 1831, the London Statistical Society was founded as early as 1825 and was publishing its own *Journal* in 1837, and the corresponding Dublin society followed somewhat later (1855). Shortly after the middle of the century, specifically in 1853, a series of International Statistical Congresses were launched, largely as a result of the initiative of Adolphe Quetelet, that until 1876 convened pretty regularly in alternate years in some European city. Their proceedings were published.

Another aspect of the increasing quantity of literature is the marked growth of periodicals. Before this period, journals that could be called professional were few and short-lived, although the *Leipziger Sammlungen von Wirtschaftlichen-policey-cammer-und finantz-sachen* was published from 1744 to 1761 and the *Ephémérides du citoyen*, published in Paris and carrying the discussion of the physiocrats, was maintained from 1765 to 1772 and from 1774 to 1776 under the title *Nouvelles éphémérides économiques*. A German endeavor to sustain publication of similar materials, issued under the title *Ephemeriden der Menschheit*, carried action along to 1782. If we look on the *Journal économique* (1751–1772) and the *Gazette d'agriculture, commerce, arts et finances* (1776–1781) as in part supplementing the *Ephémérides*, it is obvious that professional publications did flourish for a quarter of a century in France's *ancien regime*.

Thereafter came a considerable hiatus. The *Journal of the London Statistical Society* was one of the first items in the new crop: the semiprofessional *Journal des économiques* and *London Economist* were launched in the early 1840s, the publication activity of the American Social Science Association started in the middle 1860s, Conrad's *Jahrbücher für Nationalökonomie und Statistik* began in 1863, and the *Jahrbuch für Gesetzgebung, Verwaltung und Rechtspflege* (which later became *Schmoller's Jahrbuch*) in 1877. However, organized professional publication in the English-speaking world had by and large to wait until the decade of the 1880s and later years.

One phenomenon in the 1785–1885 century marked that century as at least quantitatively unique: the reprinting of earlier materials. The Italians provided the startling example. Beginning in 1803 and continuing

through 1816, they produced an amazing 50 volumes that they entitled *Scrittori classici italiani di economia politica*. A sequence of reprinting and translation efforts which took place after 1850 produced five more series with 71 volumes. Between 1840 and 1848, a *Collection des principaux économistes* was published in France, running to 16 volumes, whereas in England, McCulloch edited a half-dozen volumes of “early” or “scarce and valuable” tracts on “economical” subjects. A German, Reinhold Pauli, unearthed and published *Drei volkwirtschaftliche Denkschriften aus der Zeit Heinrichs VIII* in 1878. The background was being laid for professional economics.

Carpenter has pointed out that “not until the nineteenth century is well along does one find bibliographies compiled by historians for historians.” He then identifies several landmark bibliographies. The first general bibliography of economic literature of this period is John Ramsey McCulloch's *The Literature of Political Economy: a Classified Catalogue* (1845), based on his own library.

The first attempt at a comprehensive historical bibliography of a nation's economists was Manuel Colmeiro's *Biblioteca de los economistas españoles de los siglos XVI, XVII, XVIII* (1880), [while] Luigi Cossa's *Saggi bibliografici di economia politica* (1891–1990, reprinted 1963) made a good start at doing for Italian economic literature what Colmeiro did for Spanish.^[4]

In these same decades, the volume of business publication increased rapidly in the United States to cover a great geographical spread and the lack of any predominant city as in England or France. The start came in the form of prices currents, but not long thereafter arose journals of wider characters, such as the *General Shipping and Commercial List* at New York, soon the *Shipping and Commercial List and Price-Current* (from 1815 onward), the *New York Journal of Commerce* (1827 onward), even the *New Orleans Price Current* (1822 onward) despite its name. These were followed by specializing periodicals: the *American Railroad Journal* and *Advocate of Internal Improvements* (1832–1838 and succeeded by organs of somewhat similar titles); the *Banker's Magazine* (founded in 1846); before the Civil War, a number of peculiarly American aids to the businessman, banknote detectors; but also journals that pertained to mining, iron manufacture, and shoes and leather, beyond Hunt's *Merchants' Magazine*, already cited.

Activity in England was much more limited and still less considerable on the Continent. England did have agricultural journals, Herepath's and other railway periodicals, a *Mining Journal and Commercial Gazette* that began in 1835, and a *Bankers' Magazine* that started 2 years prior to the American one of similar name. Perhaps the localization of merchants in specific regions in London—Mark Lane, Mincing Lane, etc.—was adequate for much

communication; and mercantile newsrooms may have helped. Perhaps commodity bourses on the Continent served similar purposes.

For the most part, a single agricultural journal served England; but the United States had a journal for nearly every region: the *New England Farmer* (1822 onward); the *New York Farmer* (after 1828); the *Southern Farmer* and the *Prairie Farmer* (launched in 1840 and 1841, respectively); and others.

Two developments in the decades between 1780 and 1880 were of great magnitude: the rapid expansion of materials published by new organizations and the increase in the international flow of ideas.

Note has already been made of the East India Company, the Board of Agriculture and Internal Improvement, and the like. The number of such organizations was greater in the United States than in any other country. Societies for the promotion of agriculture were soon joined by those devoted to the promotion of manufacturing and the “useful arts.” There were the private corporations (turnpike, canal, and railroad, particularly) that sought to keep in touch with their stockholders and with customers. By 1880 the volume of publications produced by American railroads was already considerable: not only annual reports, but indentures, leases, and other financial documents; freight tariffs; timetables; advertisements of lands for sale; even occasional public relations pieces. There were the periodicals stimulated by private enterprise, and there were publications flowing from trade associations, chambers of commerce, stock exchanges, labor unions, credit reporting agencies, and other bodies.

A start in company histories had been made in the decades before 1780, but the period between that date and 1880 witnessed a significant expansion of output. Occasionally, these documents arose from conditions of distress, as when Caleb Eddy wrote a sketch of the Middlesex Canal in 1846, when the enterprise was suffering from competition of the Boston and Lowell Railroad. Usually, they were sponsored—at least blessed—by individual firms as a tribute to their successful existence over a substantial period of years. Such were Ludwig Wachler’s *Geschichte des ersten Jahr-hunderts der Königlichen Eisenhütten-werke in Malapane* (1851) or Henry Domett’s *Bank of New York* (1884). Historical accounts prepared by competent scholars who endeavored to write objectively were yet to appear.

Somewhat the same can be said of businessmen’s biographies and autobiographies which were usually efforts at praise or self-justification. Such were Stephen Simpson’s *Biography of Stephen Girard* (1832) or Bethel Henry Strousberg’s document, *Dr. Strousberg und sein Wirken* (1876). There was quite a rash of such biographies in France: biographies of Laffitte (1884), several on the Rothschilds (1846, 1847, 1868, and 1869), François de Wendel (1851), Casimir Périer (1858), and a dozen others. The flow diminished after 1870 and has never really

increased much in later decades. Businessmen’s biographies have never amounted to much in England; they were infrequent in the United States before 1890. An interesting number of collected biographies, written generally in a popular vein, did appear; e.g., Smiles’s lives of George Stephenson (1868) or Boulton and Watt (1865), and the collection entitled *Men of Invention and Industry* (1884) in England; Otto Spamer’s *Buch berühmter Kaufleute* (two series, 1868 and 1869); and Freeman Hunt’s *Lives of American Merchants* (1858) in America. Perhaps again the ground was being laid for higher grade performances later.

The international movement of ideas and materials had been indicated by the acceptance by German scholars of Petty’s “political arithmetic,” or the Italian translation and publication of works of non-Italian authors. However, movement in the nineteenth century appears to have been much enhanced. Relative to Swedish economic development of that century, e.g., Professor Heckscher stated that “perhaps the most fundamental change of all was the tremendous increase in the international exchange of scientific and technological information.”^[8]

There had been occasional translations of economic and business items in the earlier centuries, especially the eighteenth: Garzoni’s *Piazza universale* (1st Italian, 1585; German edition, 1619); Savary’s *Parfait négociant* (1st French, 1675; German, 1676); Savary des Bruslons’ *Dictionnaire universal de commerce* (1st French, 1723–1730; English, 1751–1755; Italian, 1770–1771); Mandeville’s *Fable of the Bees* (1st English, 1714; French, 1740); or Arthur Young’s *Political Arithmetic* (1st English, 1774; French, 1775). Such movement was slow, with more international movement of items at the business end of the spectrum than at the economics end.

Adam Smith was important in helping to break down international barriers. Steuart’s *Inquiry into the Principles of Political Economy* (1767), to be sure, was translated into the German promptly, appearing in 1769–1770. Smith’s contacts were closer to France, at the time a more advanced country than Germany. Smith brought a foreign body of thought into English economic thinking for the first time in history. His *Wealth of Nations* was especially welcome in France. Before the end of the century, nine editions had been published in French, and editions had appeared in the United States, Ireland, Italy, Germany, Switzerland, Spain, France, Denmark, and the Netherlands. Excerpts appeared in Sweden in 1799 and a translation appeared in Russia in 1802–1806. Ricardo seems not to have been influenced by non-English ideas, but communication did increase more or less steadily in the decades between 1780 and 1880.

One vehicle of that communication was the international congress, which not only provided for verbal exchanges of ideas during its sessions but also left behind published proceedings or other documents. There was a “Congrès des économistes” in 1847, one on “réformes

douanières” in 1856, one on “propriété littéraire et artistique” in 1859, meetings of the International Association for Social Progress in 1862–1865, an International Commercial Convention in 1868, and a series on “Sunday rest” beginning in 1876.

Another vehicle of communication among countries was the international exhibition. Elkanah Watson was the “father” of our agricultural fairs, which were initiated in 1810. Customarily, a report of some sort was issued covering the awards. Fairs are alleged to have been organized earlier, but little is known about them. Quite surely they produced no published residuum. One held in France in 1798, organized by M. de Neufchateau and devoted to French industrial productions, did yield a report, drafted by M. Chaptal. And there was a succession of such exhibits until the eleventh in 1849.

The Grand Exhibition of 1851 in London in the Crystal Palace was truly international in scope and set the pattern for Philadelphia in 1876 and Chicago in 1893. These gatherings with their displays of machinery and products did much to promote industrial communication and left behind a considerable literature in the reports of judges and in the findings of delegations from foreign countries. Documents published on Philadelphia’s Centennial Exposition of 1876 ran to more than 20 volumes.

Two features of the decades between 1780 and 1880 pertain to quality of output. One might be construed as a development from “political arithmetic,” the graphic presentation of statistical data. The innovator was William Playfair, who in 1786 published his *Commercial and Political Atlas*, which was followed in 1801 by his *Statistical Breviary*. In these and other works of Playfair, one finds several varieties of diagram: line, bar, and pie.

The employment of diagrams expanded rather slowly, however, and their popularity came more in France than in their country of origin. Playfair’s first book was translated into French, where it appeared under the title of *Tableaux d’arithmétique linéaire*, almost as if it were a study in method rather than a “commercial and political atlas” of England. Quetelet and other French vital statisticians made use of graphs and so did the French government engineers having to do with public works and with transportation. C.J. Minard composed the first memoir on the graphic method in 1861, and E.J. Marey composed a notable text on *La Méthode graphique* 1878. Funkhouser calls the period from 1860 to 1890 “the golden age of graphics...marked by the unrestrained enthusiasm, not only of statisticians, but of government and municipal authorities.”^[7]

The other qualitative change in the 1780–1880 period is that of economic thought. What Adam Smith had started, the generation of Ricardo, Malthus, James Mill, and Jean-Baptiste Say advanced further. As Professor Rogin put it, “Ever since the advent of economic science as a separate academic discipline there has existed an impulse to model it in the alleged image of an exact

natural science and thus to evade both the intractability of history and disagreement as to values.” From the physiocrats and Smith came the competitive equilibrium; and this provided the basis of abstract elaboration of principles in the nineteenth century, especially the roles of the different factors of production.^[9] Already in the first quarter of the century, Say was complaining of his contemporary, Ricardo, that the latter was “drawing all his results from a small number of principles, putting or leaving aside all others.” He thought his case to be all the stronger because he believed Ricardo through his method “arrived at results different from the real state of the case.”^[10] Also it may be significant that in the generation after Ricardo and James Mill, economists began to be concerned with their own procedures. John Stuart Mill published in 1843 his *Logic* in which he exposed “the methods of physical sciences as the proper models for the political”; John Elliot Cairnes wrote his *Character and Logical Method of Political Economy* in 1857; meanwhile, the “historical school” in Germany had begun its creative response to the intellectual methods of the English proponents of political economy; and as late as 1891, John Neville Keynes, the father of John Maynard, issued a well-received volume on the *Scope and Method* of his subject. And in the 1870s and 1880s appeared the first substantial group of histories of economic thought—books that, unlike Blanqui’s of 1842, dealt almost wholly with the abstractions and concepts that had sprung up in the preceding century.

These changes in the intellectual apparatus of economists apparatus of economists indicated an enhanced sophistication. In the eighteenth century and earlier, political economy had been largely a set of rather specific rules, not very broadly entertained, all more or less slanted toward spelling out the roles that individuals could play in the promotion of a richer, somehow better economy. In the nineteenth century, more and more came the increased regard for imponderable, impersonal forces—maximization of profits, the interest rate, demand and supply, etc.—with at least an implied dichotomy between political and business economy. By reason of the change in the quality of political economy in the nineteenth century, a professional literature evolved within those decades—in the era, say, between David Hume and Alfred Marshall.

The Fourth Period

The final period, extending from about 1885 to the present, has been marked by a greatly increased volume of publication in the field, by enhanced professionalization in the ranks of economists, and by a revolution in the area of business administration and its literature.

The extraordinary enlargement of economic and business literature in the last century has resulted from the operation of many forces: the alterations in printing technology; the changes in the publishing world; growth in the field of communication commanded by governments;

increase in the number and variety of private organizations active in publication performance; and transformations of thought within both economics narrowly construed and business administration similarly viewed. There has also been a geographical expansion. Countries such as Canada, Australia, or Sweden were publishing relatively little in the field in the 1880s.

Publishing houses have contributed to the whole movement through their creative activities. Institutions, such as McGraw-Hill or Simmons-Boardman, were set up originally by innovating entrepreneurs. It was to the advantage of the publishing concerns to have more readers and the information they purveyed proved to be advantageous to the readers. Improved operations of business institutions, higher profits of the purchasers, meant in turn greater demand for the publisher's products. Beyond this, publishers were frequently creative by virtue of the missionary zeal for reform. Henry Varnum Poor waged almost continuous war against evils or in advocacy of reform while he was editor of the *American Railroad Journal*. The Simmons-Boardman Company promoted through its periodicals such improvements as standardized threads for bolts and nuts and standardized design for automatic coupling for railroad vehicles. The *American Journal of Mining* sponsored the American Bureau of Mines. This was good business for the economy as a whole, and it helped to swell persistently the volume of business literature.^[11]

The change from laissez-faire to welfare government meant a tremendous increase in governmental production of literature concerned with economic and business affairs. Particularly pertinent is the conversion of occasional investigatory efforts into persisting regulatory ones, with a marked enhancement of literary output. Already this change had occurred in England relative to railroads. It came in the United States primarily after 1880. The Windom and Cullom Committees that inquired respecting railroads were followed by the Interstate Commerce Commission. The Aldrich Committee of 1891–1893 and the National Monetary Commission of 1909–1910 were succeeded by the Federal Reserve Board. In the end, the country possessed not merely these agencies of regulation but the Federal Trade Commission, the United States Tariff Commission, and numerous others equally well staffed and equally capable of issuing orders and regulations and special reports as well as the stock annual ones.

National governments have also become “service” states, assuming an obligation to provide freely, or at low cost, data essential or convenient for policy formation in agriculture and business, for public appraisal of economic and business affairs, etc. Such data are useful to various federal governmental agencies, but chiefly it has value to economists and businessmen scattered over the country. This is true of much work performed by the Bureau of Standards, the Department of Agriculture, and the Library of Congress. The American state governments have been equally active, or nearly so.

The enlargement of the flow of literature from private institutions has been particularly great in the United States. The decades since 1880 have witnessed notable increases in the number of trade associations, chambers of commerce, cooperatives, produce exchanges, and the like. But now international chambers of commerce, organizations of bondholders or taxpayers, and many other new institutions issue publications, especially periodicals or other serials.

Important with respect to volume and quality have been the new professional organizations and educational institutions. To the local statistical societies above noted were now added national economic and statistical associations in many countries: the *Nationalekonomiska Föreningen* (or Economic Society) launched in Sweden in 1877, the Royal Economic Society set up in England in 1888, the American counterpart founded the next year, down to the International Economic Association organized subsequent to World War II. In the field of business the launching of new institutions has been even more noteworthy, especially in the United States: the American Association of Public Accountants in 1887, the National Association of Credit Men in 1896, the Advertising Federation of America in 1905—and on down through the decades organizations of industrial advertisers and controllers, of sales executives and management engineers.

Schools of business have also manifested a capacity for publication. The area of business management possessed few established facts when the first schools of business were established. The Bureau of Business Research set up by the Harvard School and the Department of Industrial Research launched by the Wharton School were early responses to this situation.

Note should be taken of corporate research agencies, organized separate from governmental or educational institutions, and the financial foundations that have promoted research in the economic and business field. Both are largely the children of twentieth century United States. The research agencies have been varied in character. One early group (rather loosely organized) was devoted to the promotion of a series of studies in American economic history. The financial support came from the Carnegie Corporation of Washington, and the studies were published by it—of which the best known are Victor S. Clark's three volumes on our manufacturing industries and L.C. Gray's two volumes on Southern agriculture before 1860. Somewhat later came the International Committee on Price History, financed by the Rockefeller Foundation and constituted of representatives from several interested countries under the chairmanship of Sir William Beveridge. Institutions with centralized research staffs have arisen: the National Bureau of Economic Research, the Commonwealth Fund, and the like. Some are loosely connected with educational institutions as the Food Research Institute at Stanford or the Scripps Foundation for population research at Miami University.

Their publications bear the implied and sometimes the explicit indication that the specific item has been developed with aid from the whole body of scholars attached to the institution and perhaps issued only after criticism by another body of scholars. The day of the individual scholar has not passed, but such institutionalized research was unknown a half century earlier.

As for the financial foundations, all that one need note is that the funds supplied by the Rockefeller, Carnegie, Ford, and other such bodies have permitted and stimulated research and publication in a measure undreamed of prior to World War I. The impact has been largely in this country, but more recently moneys for these purposes have gone abroad from the same foundations.

Not only has the volume of economic and business literature expanded in an extraordinary degree, but the general complexion of that literature has undergone revolutionary changes.

In some measure, to be sure, there was persistence of trends, such as in the matter of continuity or accumulation. By the later decades of the nineteenth century, it had become an almost universal practice for writers in the economic and business field to consult previous writings. By the twentieth century, it had become a test of scholarly quality that a man remember whence he had borrowed significant ideas or important statements of fact. The growth of national libraries, such as the British Museum or The Library of Congress, and of university and large public libraries, comes chiefly in the past three quarters of the century, especially in the United States. Cumulation has been promoted by large bibliographical works such as Gregory's *Union List of Serials*, Stammhammer's bibliography of socialism and communism, or Daniel C. Haskell's "check-list" of early European railroad literature. Cumulation has also been fostered by service departments of national governments or private research organizations. Information is collected and hoarded in such governmental agencies as the American Bureau of Labor Statistics or Bureau of Agricultural Economics. It is also assembled and hoarded by organizations such as the National Bureau of Economic Research or the Brookings Institution. Now no one on its staff launching work on almost any historical theme need really "start from scratch."

There was also continuity from past eras in the persisting effort at measurement. The statistical work of governments increased, and there was marked enlargement of activities on the part of private organizations. Here again the United States has taken the lead with such reporting agencies as Dodge on building construction, Cram on automobile production, Dun & Bradstreet on business failures, or Dow-Jones on stock market movements. The measurements recorded by the quasi-private, quasi-public Federal Reserve Banks make the expansion of recent decades even more striking.

Changes in the character of economic and business literature since 1880 may also be pictured correctly as

proceeding from tranquility to profound disturbance. Optimism, general agreement on principles, calmness of exposition—this was the economists' "era of good feeling." Something of this spilled over into the twentieth century in the writing of such an economist as Thomas Nixon Carver. In the meantime, business had settled into a belief in the necessity of learning only by doing; experience was not merely the "best," but really the only teacher.

Of course, troubles of various sorts were already brewing. Marx and Engels had formulated their "manifesto," and Marx was busy writing in the British Museum. More immediately important, Jevons, Walras, and Menger were introducing ideas of marginal utility. And still more unsettling, at least over the intermediate future, Walras was hatching his general equations, and with Pareto was introducing mathematics into the previously common-sense field of economic theory. In the same years, "practical" problems were causing controversy: bimetallism, the return of protectionism, social insurance, regulation of railroads, spread of labor unionism, and the like. The world of economics seemed to grow ever more complex.

Efforts to solve some of these problems gave encouragement to the advocates of measurement and to those who were moved to improve the science of statistics. On the whole, the protectionist-free trade controversy and that surrounding monetary affairs did not lend themselves to much quantitative handling. The field of social insurance was also somewhat infertile in this regard. However, the governmental bureaus charged with the supervision of railways in England and on the Continent collected statistical data with avidity. Some of the earliest treatises in the field, such as Gerstner's out of Austria or Audiganne's out of France, displayed a considerable bias toward quantification. And the Interstate Commerce Commission was issuing statistical volumes with its formation in 1887.

Sometimes a measurement-resisting subject would yield indirectly at least to quasi-statistical treatment in the hands of an intellectual innovator such as Professor Taussig who spoke of the "verification" of the theory of international trade under the "abnormal" conditions of dealings between a gold-standard and a paper- or silver-using country.

The study of business cycles represented most clearly the convergence of trends. Juglar demonstrated the existence of cycles in his examination of bank data from France and England (1860) in quantitative data. Subsequently, the tendency in the treatment of the subject—by Jevons in 1875, the American Frederick B. Hawley, Hull in his handling of building cost data, and preeminently Wesley C. Mitchell in his pathbreaking volume of 1913—was for an ever-increasing reliance on measurement. The literature concerned directly or indirectly with the business cycle would cover many running feet of library shelving, constituting a "bulge" from the trend line for this period.

Concurrently with the study of the business cycle had gone a considerable expansion in the exploration of

population trends and of the associated field of actuarial science. International congresses, professional journals, a series of examinations for advanced standing, and the like have created a literature within a literature.

Not least important has been the development over the past few decades of statistical inference—with its literary products. The advances here have been linked closely with the name of R.A. Fisher of England, whose *Statistical Methods for Research Workers* (1925) and *Design for Experiments* (1935) led the way. Fisher asked what could be learned about a “universe” or aggregate from a sample out of it and whether a sample could be selected out of the universe that would display the characteristics of the whole, or characteristics with recognized deviations from the whole. Out of this line of thought has grown quality control in business, opinion research in business and elsewhere, and the like—with another sizeable addition to the volume of economic–business literature.

In the area of economic theory a noteworthy change has occurred—especially as far as the English-speaking world is concerned. In the preceding period, Cournot, Walras, and Pareto emphasized that the ideas of the theorists could be expressed clearly and precisely in mathematical language. Marshall, Edgeworth, Irving Fisher, and Pigou helped to introduce this language into England and the United States, whereas more recently still, the developments in this area and in statistics have coalesced to produce econometrics, and these three in turn, with the ideas on national income stemming from Keynes, to yield model building, linear programming, and the like. By a more direct route from the mathematical “fathers” has come Professor Leontief’s input-output analysis and the work that this innovation has promoted.

Twentieth century bibliographies in this field, Carpenter states, “have been compiled [to] cover all the subjects generally falling under the heading economics, rather than just the writings of economists or the literature of public finance [with] a greater emphasis on the ephemeral literature.”^[4] Henry Higgs, setting himself the goal of listing books in all Western languages, produced the important *Bibliography of Economics, 1751–1775* (1935). Magdalene Humpert’s *Bibliographie der Kameralwissenschaften* followed in 1937 and a major French work, *Economie et population, les doctrines francaises avant 1800; bibliographie générale commentée*, was issued by the Institut national d’études démographiques in 1956. L.W. Hanson’s *Contemporary Printed Sources for British and Irish Economic History, 1701–1750* (1963), reaches a new height in economic bibliographies, according to Carpenter.

Another significant aid to scholars is the *Catalogue* of the Kress Library of Business and Economics at the Harvard Business School, which has been issued in four volumes between 1940 and 1967.

A novel development of the era since the 1880s is the publication of “festschriften.” Action of this sort suggests respect for the subject of the honor and a high appraisal of

the results of research. Such publications began to appear in Germany in the latter half of the nineteenth century, and the example was followed in Italy, Scandinavia, the Low Countries, the United States, and less so in France and England.

A second novelty was the publication of manuscript material. There had been printing of governmental materials for some time—national and local, administrative and legal—and some of the first publications in our field were so constituted, or were largely so, e.g., documents in Schmoller’s study of the Strassburg cloth gild (1879), Hintze’s compilation relative to the Prussian silk industry (3 vols., 1892), Hayem’s *Mémoires et documents pour servir à l’histoire du commerce et de l’industrie en France* (12 series, 1911–1929), even Bland, Brown, and Tawney’s *Select Documents* (1914). The publication of private papers has come chiefly through the printing of documents from the archives of such historic institutions as the East India Company and the Hudson’s Bay Company.

Literature which pertains specifically to the operation of business institutions had in these decades since 1880 been going through no less extraordinary an experience. There had been manuals that told the merchants how things *are* done—what weights, what types of money, what procedures, and the like; and occasionally a manual as to how things *should* be done. In the latter category would fall the books that linked religion with business activities. As early as the sixteenth century, John Browne’s *Merchants Avizo* (1588) had given instructions to young merchants going to Spain and Portugal. Soon there were the manuals of Savary and Kruse, of Malachy Postlethwayt and Wyndham Beawes, descriptions of what was done and sometimes advice on the best among several possible practices. Even in the nineteenth century, with Babbage and Freedly and others of the midcentury, there was very limited conceptualization of business functions.

A break appears to have come in the 1880s. We know that Henry Varnum Poor and some of the American railroad executives had had ideas relative to their industry as far back as the 1850s. A new, broader, more vigorous start came in the 1880s, largely through the American Society of Mechanical Engineers. From this background came Frederick M. Taylor and what in 1905 rose to be labeled “scientific management.” In these years, too, books of a new character were beginning to appear in England. There was J. Slater Lewis’ *Commercial Organization of Factories* (1896), F.G. Burton’s *Commercial Management of Engineering Works* (1899), and somewhat later, E.J. Elbourne’s *Factory Administration and Accounts* (1914). In general, the English approach was more largely accounting and commercial control than the American. In France, Faye was making a major contribution in his materials on the functional organization of business operations. And the Germans made at least an indirect contribution in the “line” and “staff” organization of their army.

These steps represented a forthright belief that generalizations, abstractions, perhaps “principles,” were possible

with respect to business structures and performances. The abstractions were those of business functions (marketing, production, finance, etc.), which tended to make all business institutions into an “extended kinship group,” if not into one closely knit family.

In step with the changing climate of opinion in the business world, there was the initiation of specialized training in business at the college and university level: the Wharton School of Finance at Pennsylvania, the Amos Tuck School at Dartmouth, and that on Business Administration at Harvard—with a rapid increase in popularity at other universities in the years after World War I. And a specialized literature began to flourish. Mr. Arch W. Shaw had launched *System, Business*, and other publications in the field. Other publishers kept close pace and books of professional character began to appear: Hatfield’s quasi-classic *Modern Accounting* (1909), P.T. Cherington’s *Advertising as a Business Force* (1913), and a small flood of items on scientific management.

Business literature has flourished most luxuriantly in the United States. Germany has been a rather distant second, although vigorous in the theoretical phases of the field, with England, France, and other countries less involved. The general attitude in England has been that one could not learn business out of books.

In the United States, the growth of the literature has been notable for its increased sophistication and its changed time perspectives. Business literature reveals an increasing concern with the future. The introduction of budgeting, of market analysis, of employee training or executive development, etc., has turned businessmen’s eyes increasingly toward the future; and a whole new stream of literature reflects this change. The field of business has also developed a sophisticated *historical* interest. Histories of individual business units and business functions had appeared intermittently over past centuries, but the conscious effort to create a new branch of historical study and writing relative to the operation of individual business enterprises may be regarded as a contribution of Dean Wallace B. Donham of the Harvard Business School (who brought Professor N.S.B. Gras to that institution to implement his ideas) and their imitators and admirers of that period. An almost contemporary development—seemingly independent—occurred in Germany under the inspiration of Professor Kurt Wiedenfeld of Cologne.

A number of factors have encouraged the preparation of histories of companies: increasing longevity, which makes possible semicentennial or other anniversary volumes; an improved sense of public relations; sometimes the aroused curiosity of scholars; sometimes the letter of the tax laws, etc. Increasingly, at any rate, the flow of company histories has broadened and the quality risen. Nor is the enhancement in volume and quality restricted to merely the United States and Germany. By and large, England and France have lagged behind (except for

histories of banking institutions in the former), but to their output must be added quite a flood from the Netherlands and Scandinavia.

Beyond businessmen’s biographies there have been studies of business practices and institutions other than individual houses: methods of dealing in foreign exchange, the commercial paper market, trade associations, and the like—even the businessman as a social creature.

CONCLUSION

This survey of the evolution of economic and business literature suggests that a narrowness in the concept has dominated the histories of economic thought. The wide-ranging literature reflects, for the Western world as a whole, the changes in the entrepreneurial and governmental systems over the centuries. Economic and business literature constitutes a connecting link between economic and business performance and the realm of ideas. It throws light, too, on the formation of public opinion and the relation of that opinion to social action. The differences in rates of economic change among nations are of increasing interest among scholars, and here, too, a study of economic and business literature may prove of value. There is recognition that economic sophistication is a prerequisite to forward-looking public administration and that there are forces and conditions in business life not adequately taken care of in the economists’ abstractions. Again, the materials for a history of economic and business literature are those also for a history of economists, or of explorers and innovators among economic historians. No less than in medicine or natural science, this literature seems to manifest a tremendous increase in the volume of communication, an evolution and testing of new ideas, and a marked advance in sophistication.

The above article draws heavily upon a longer consideration of the topic by Arthur H. Cole, which was published first under the title “Conspectus for History of Economic and Business Literature” in the *Journal of Economic History*, 17(3), (September 1957) and, in a slightly revised version, under the title *The Historical Development of Economic and Business Literature* (Publication #12 of the Kress Library of Business and Economics, Graduate School of Business, Harvard University, Boston, 1957).

Electronic Records Preservation

Robert P. Spindler

Department of Archives and Manuscripts, Arizona State University, Tempe, Arizona, U.S.A.

Abstract

The need to preserve electronic records and publications has been expressed in archival and library literature, but analysis of the challenges and development of strategies for achieving reliable retention are in their infancy. Many archivists and librarians perceive that information created in or converted to electronic form is at risk as a result of several notable losses of important electronic information like National Aeronautics and Space Administration's electronic files from the 1976 Viking mission to Mars, pre-1997 e-mail communications of U.S. Vice President Al Gore, and photographic image files damaged by the "I Love You" virus in 2000.

WHAT IS AN ELECTRONIC RECORD?

Electronic records can include information originally created in an electronic format or information created in hard copy or analog format and subsequently digitized through use of digital imaging, optical character recognition technologies or direct analog to digital conversion for audio and video information. Electronic records can include digital image files, audio files, and geographic information system files, as well as the more common documents produced by word processing or e-mail. Compound documents may include several of the above technologies in a single product.

An electronic record is a form of information produced in the course of an event or a routine activity by an individual or an organization. Electronic records are created and retained as specially designed output from an information system or personal computer. They may be selected for retention because of their comprehensiveness and portability, or they may not be retained since other forms of the same information (e.g., hard copy, microfilm) may be preferable for personal use, acceptable as evidence, or retained at lower cost. Most files output or saved from information systems or personal computers are not electronic records. Simple backups or downloads usually do not contain sufficient contextual information to authenticate and verify the accuracy of the content.

Connecting Content and Context

For many years, archivists have struggled to understand and explain the difference between an electronic record and electronic information or data. Archivists have made important distinctions between the content of information and its context, since elements of the context of information creation can certify the accuracy and authenticity of information content. Context is also essential for documenting how and when content changes have been

made over time. Electronic records must have content *and* context in order to successfully document an event, an activity, or a business transaction.

Electronic publications often serve as a record of an activity or transaction since they generally are presented with attributions of authorship and sources. They are often granted the status of records because authors, footnotes, and bibliographies provide sufficient context for readers to have confidence in the accuracy and authenticity of the information presented. Other electronic information products such as specially formatted output from a large information system are intended to serve as records, but often that output does not include the contextual information necessary to be considered a reliable record of an event or transaction. Much of the research in electronic record preservation has centered on identifying the contextual information necessary to authenticate the content of an electronic record.

History of Electronic Records Preservation

Early attempts to collect and preserve electronic records began with the establishment of data libraries that supported social science research in the 1970s. These projects generally concentrated on retaining textual and numeric research data in a software-neutral form for access and reuse. Although certain quality control tests were conducted and error logs were investigated, it was the mission of these institutions to retain data derived from specific research projects to facilitate subsequent reuse and research replication. Contextual information about the data was generally retained in separate data dictionaries and codebooks that described the functions and allowable data values for specific pieces or fields of information.

The U.S. National Archives received its first accession of electronic records in 1970, and this function was retained through several reorganizations to this day. The current

Center for Electronic Records physically acquires and preserves similar textual and numeric data sets produced by government agencies and does not generally retain electronic records in software-dependent formats. The center and its predecessors developed and implemented standards for selecting and accessioning electronic records, conducting quality control tests, and establishing public access services.

As more electronic content was produced with the advent of inexpensive personal computers and mainframes in the 1980s, computing professionals established facilities and routines for system backups. They generally did not consider long-term retention other than content presented in computer output microfilm (COM). Quite often the labeling on COM sets and backup tapes was not sufficient to describe the scope or age of the content within. At the end of this decade, electronic reformatting technologies such as digital imaging became widely available and many institutions implemented imaging to reduce paper record storage costs. Legal standards were soon established for certifying the accuracy of digitally reformatted content, but these standards generally focused on documenting imaging and quality control as routine business practices for litigation defense support.

In the 1990s, e-mail and word processing became essential features of business and personal life, and questions of the accuracy and authenticity of electronic records began to emerge in highly publicized cases of fraud and unauthorized system security breaches.

The landmark 1993 U.S. Court of Appeals decision in *Armstrong versus Executive Office of the President* highlighted the challenges of increasing government efficiency through technology, while retaining citizens' right to access government records. The decision confirmed that, in this case, e-mail did constitute a federal record that must be retained or destroyed in accordance with the Federal Records Act. The court also ruled that printouts of White House e-mails did not contain sufficient structural and contextual information to authenticate the communications and that the electronic version of the communications needed to be retained to satisfy federal record-keeping requirements.

In the next few years, widespread availability of digitization technologies and production of electronic books, journals, and indexes enabled the development of digital libraries that presented locally owned and commercially licensed content made accessible through the Internet. The opportunity for development of digital libraries caused librarians to take a more active interest in preservation for electronic publications and establishment of metadata standards to support Internet resource discovery.

In 1997, the Virginia Institute of Technology (Virginia Tech) initiated the first university program to accept electronic theses and dissertations. This project highlighted the similarities between librarians' concerns for preserving electronic publications and archivists' interest in

preserving electronic records. Theses and dissertations are simultaneously considered a publication and also a student record. As a result of the Virginia Tech initiative and in response to the 1996 Research Libraries Group report *Preserving Digital Information*, archivists and librarians began to study the relationships between content and context. Academic research on these issues emerged with the support of the National Historical Publications and Records Commission, a division of the National Archives and Records Administration that made electronic records research a funding priority throughout the 1990s.

Beginning in 1989, Luciana Duranti of the University of British Columbia published a series of articles in the journal *Archivaria* that examined the applicability of diplomatics for modern record-keeping practices. Diplomatics was a mid-seventeenth-century discipline that viewed the character and content of individual documents, as well as the organizational context of document production, as indicators of document integrity and authenticity. Intrinsic and extrinsic elements of particular documentary forms are cataloged and used as tests of authenticity. Extrinsic elements included medium used, script, language, seals, and annotations, while intrinsic elements included document protocol, actions taken or described in the document, and final responsibility for the content.

In 1994, Duranti's interest in diplomatics and document authentication led her and colleague Terry Eastwood to establish the "University of British Columbia (UBC) Project," which defined requirements for creating, handling, and preserving reliable and authentic electronic records in active record-keeping systems. Duranti and Eastwood then collaborated with the U.S. Department of Defense to set standards for record management system requirements that are used for certifying software vendors and their products. A planned second phase of the UBC Project was intended to address long-term preservation of inactive electronic records, but the scope of such a project required a larger and more diverse research team. As a result, the "InterPARES" (International Research on Permanent Authentic Records in Electronic Systems) project was launched in 1999, an international research initiative in which archivists, computer engineers, national archival institutions, and private industry representatives are working to develop the theoretical and methodological knowledge required for the permanent preservation of authentic electronic records.

Meanwhile, in 1991, the Minnesota Historical Society hosted the "Working Meeting on Research Issues in Electronic Records," which established the National Historical Publications and Records Commission's research agenda for electronic record keeping. In response to this agenda, Richard Cox of the University of Pittsburgh launched a three-year project, beginning in 1993, to establish functional requirements for record keeping in electronic information systems. The project also investigated several

related topics including organizational culture, technical capabilities of existing software, utility of standards and policies for satisfying archival requirements, and evaluation of technology and policy strategies.

The "Pittsburgh Project" resulted in dissemination of lists of functional requirements for record keeping, an analysis of tactics for implementing record-keeping systems, and an assessment of variables that may affect the use and implementation of those systems. In 1994, project consultant David Bearman of *Archives and Museum Informatics* and project researcher Ken Sochats asserted that the functional record-keeping requirements could be converted into formal requirements for specific metadata elements. In 1995, Philip Bantin of Indiana University began testing this model in an analysis of records systems for the Financial Management Support and Enrollment Services offices at that institution. More recently, the Australian Recordkeeping Metadata Research Project has made substantial progress on metadata issues, with record-keeping metadata standards issued by the Commonwealth, Victorian, and New South Wales governments between 1998 and 2001.

The search for electronic record preservation strategies also led to attempts to enunciate the competencies necessary for archivists, records managers, and librarians to participate in electronic preservation projects. In 1993, the Committee on Automated Records and Techniques of the Society of American Archivists established the Automated Records and Techniques Curriculum Project, and this work also resulted in the publication of a special edition of *The American Archivist* dedicated to electronic records case studies.

In addition, two annual national conferences on electronic records preservation were established. Cohasset Associates, a Chicago consulting firm established the MER: Managing Electronic Records conference in 1993, which serves as a forum for presentation of emerging preservation strategies that is widely attended by corporate and government organizations. In 1999, Arizona State University established ECURE: Preservation and Access for Electronic College and University Records, which focuses on the special record-keeping needs of colleges and universities and is dedicated to the critical analysis and dissemination of practical strategies for electronic records access and preservation.

Advanced technologies are now being applied to electronic preservation issues. In 1999, the Distributed Object Computation Testbed project was established as a partnership between the U.S. Patent and Trademark Office, the National Archives and Records Administration, and the San Diego Supercomputer Center. The test bed was developed to store complex documents on geographically distributed data archives and systems using the processing power of supercomputers to implement preservation strategies from the digital library, archival, and computing communities. Brewster Kahle's Internet

Archive established technology that finds and stores snapshots of websites from around the world in an attempt to comprehensively document the Internet. Both the National Archives and the Library of Congress recently implemented programs to collect archival snapshots of selected web pages, but none of these projects have fully addressed the potential software incompatibility and proprietary markup issues related to websites.

At the beginning of the twenty-first century, implementation of new technologies continues to advance as archivists, librarians, and technology professionals continue to work on several aspects of the electronic records preservation challenges. The Government Paperwork Elimination Act of 1998 and the Electronic Records and Signatures in Global and National Commerce Act of 2000 (known as E-Sign) mandated widespread implementation of electronic government services and electronic signatures. Similar legislation has been adopted in several state governments.

Interactive Internet technologies and the advent of virtual reality and desktop videoconferencing are increasing the complexity of electronic record keeping. Electronic content is increasingly software dependent so that long-term retention of products may require continued support for obsolete software and operating systems, active migration of records to new software, or development of emulation hardware and software. Increasing data storage capacities and the fast development and implementation of proprietary compression and backup technologies are hastening the obsolescence and increasing the incompatibility and interoperability of data storage media and systems. Widely distributed computing facilities and multi-institutional or multinational collaborations make retention and appropriate deletion of electronic records much more difficult than before. Distributed computing places greater pressure on policy, procedure development, and oversight since file maintenance is no longer centralized.

Preserving Electronic Information

Thirty years of work in acquiring and retaining electronic content has not resulted in complete solutions for electronic record preservation, but researchers have started to identify and catalog the major barriers to successful electronic record keeping. A successful electronic record preservation strategy requires attention to seven major challenges (Table 1).

Storage media

Storage media is often used to support backups, off-line storage, or distribution of electronic content. These challenges have received a great deal of attention in the popular media and the professional literature, but they are the easiest to manage since estimates of the reliable shelf life of various media and interoperability of certain media

Table 1 Seven challenges of electronic record preservation.

Challenge	Example
1. Physical degradation of storage media	CD does not read anymore since the recording surface has been degraded by air pollutants.
2. Physical obsolescence of storage media	5.25 inch floppy disc does not fit in CD-R drive.
3. Incompatibility/noninteroperability of storage media	One manufacturer's DVD disc will not play in DVD players produced by a different manufacturer.
4. Software, operating system, or encoding incompatibility/noninteroperability	New software release will not run file from old release. New software release opens old file, but contents are corrupted. Software is not compatible with operating system. Product designed for display with one Internet browser does not look the same in a different browser. Proprietary backup software and storage format not compatible with new release or other backup software. Proprietary codes from HTML editing packages do not convert to XML.
5. Human error/vandalism	Accidental or malicious deletion. Website is vandalized.
6. Backups and snapshots	Backups lost or overwritten. Wrong files backed up. Incomplete snapshot: Video server backed up, Web server not backed up. Snapshots of different servers not contemporaneous.
7. Metadata	Insufficient context to verify source and authenticate content.

formats like CD-R are available. We can project the expected physical life of the media, track changing format standards for media players, and plan to move the information to new media based on the expected physical shelf life and availability of new formats and players. The generally accepted reliable shelf life of compact discs for example is 5–100 years, depending on several factors, including manufacturer, production materials used, storage conditions, level of use, etc. However, many experts believe that physical obsolescence and incompatibility and noninteroperability of storage media occur faster than the media can physically degrade. One source reports that media players are becoming obsolete every 2 to 5 years. It is critically important to move electronic content from old storage media to newer media before the old media player fails or becomes unavailable. Commercial data conversion and recovery services and

some archival repositories retain and maintain some obsolete media players, but the usable life of this equipment is unknown.

Software and document encoding issues

Software incompatibility or noninteroperability results in files that will not open at all or documents that are corrupted and must be repaired if possible (usually through comprehensive manual reentry or manual editing and correction of content). The two major strategies for addressing software incompatibility and noninteroperability issues are known as emulation and migration.

The emulation concept proposed by Jeff Rothenberg of the Rand Corporation involves writing new software that mimics the appearance and functionality of old software. Recently, experts in this area have challenged emulation, suggesting that efforts to write emulation software solutions have not resulted in exact reproductions of appearance or function. Approximate reproductions of appearance or function might be sufficient for some record-keeping applications, provided that the information content is accurate and can be authenticated.

Migration tends to be the more widely accepted preservation strategy, in which files are regularly saved to new releases of the same software as they become available or are converted to new software produced by another manufacturer. Migration is not always successful, as conversion programs do not always have full “backward compatibility” that results in “clean” conversions between old and new software releases. Many electronic document managers are selecting ubiquitous software packages, relying upon a large “installed base” in the hope that that the manufacturer will survive for many years and that future releases will have complete backward compatibility. In addition, software manufacturers have not always supported “interoperability” by including reliable conversion programs for moving files between their own products and those of other manufacturers without corruption. Manufacturers are increasingly including backward compatibility and limited interoperability into their product designs, but, for now, migration cannot be considered a fully reliable preservation strategy.

When electronic information is encoded to support electronic publication or display on the Internet, the selection of encoding syntax or language is an important issue. Although standards for encoding electronic documents such as SGML (standard generalized markup language), HTML (hypertext markup language) and XML (extensible markup language) have been established, software developers have not always complied with the standard, introducing proprietary codes in their document-editing software. These are codes that may be misinterpreted or cannot be read by other software packages, resulting in data-processing errors or changes of document color or formatting. Color or formatting may not be essential

elements of a textual electronic record but may be significant components of multimedia presentations that incorporate graphic or video content. Proprietary codes can sometimes be replaced with their standardized equivalents but the appearance and functionality of the document could be changed as a result.

Human error and vandalism

Human interaction with electronic information presents important challenges for electronic records preservation. At a very basic level, the culture of technology transfer, adoption, and implementation makes preservation more difficult since our faith in new technology sometimes precludes critical analysis of its effectiveness. Those who would champion system design changes that support effective record keeping often are met with resistance since record keeping is often not valued as highly as fast implementation. One result of our culture is that although sound data management practices are available, systems managers for large enterprise level systems or users of desktop personal computers do not always rigorously follow them.

Electronic records can also be intentionally compromised through actions of individuals who have access to the content or have learned to circumvent data security measures. Records can also be corrupted as an intended or unintended consequence of a computer virus infection. An individual can compromise any encryption and security technology with access to specialized expertise and high-performance computing facilities. Often, violations of system security are undetected until damaged content or other evidence of the violation is subsequently discovered. These threats to electronic record keeping can be minimized through the retention and maintenance of off-line backups.

Backups and snapshots

Reliable backups of electronic records are essential for successful short-term retention since data can easily be deleted or corrupted with the push of a button. Redundancy has always been a very successful preservation strategy and inexpensive data storage can make redundancy cost effective. Backups are intended to support recovery from disasters, system failures, or human error, but many data losses can be attributed to improperly managed backups.

Backup failures can result from improper backup system configuration, lack of quality control, failure to migrate the content before backup system failure, incompatibility with new backup systems, or simple operator command error. Most backup systems use proprietary compression and software that has a very high degree of noninteroperability and incompatibility. In addition, the rapid increases in storage technology capacity and the

increasing frequency of new backup software releases make long-term survival of backups unlikely. Accurate file backups must be made to a nonproprietary and compressionless environment, and they must be effectively migrated or emulated for successful long-term preservation. The timing and scope of backups should be established in advance, rigorously followed, and tested for accuracy and completeness. Many experts believe that given the risks, backups are not effective for record keeping. Migration of records to a specially designed record-keeping system or redundant live-server storage may be more reliable, especially for long-term retention.

Specially designed downloads of websites known as “snapshots” are key issues for preserving a record of an interactive website since their scope and timing are critical for capturing a “record” of the changing content. Many complex Web products are now stored on a number of different servers to facilitate efficient retrieval and display. The products themselves only exist for a moment in time on a patron’s computer screen, but the sources of the content are distributed. All the source files of product components must be included in the snapshot so that the record of the website is complete, unless certain parts of the content are deemed “nonrecord,” such as the chat room attached to an electronic college course.

The timing of snapshots is also important since an interactive website may have certain components that are static and others changing. Snapshot timing needs to be established with some attention to the rate and nature of change in the website. Ideally, the snapshot of the record components across a series of servers should be done contemporaneously so an accurate record of the components and their relationships can be retained.

Metadata and retention of context

The essential difference between data or electronic information and an electronic record is that electronic records have information content *and* specific pieces of contextual information that authenticate or explain the content. This contextual information is called “metadata.”

In general, metadata tags or “metatags” are elements of textual information inserted into the header of an electronic file to enable automated searching, retrieval, and use of the content within the file. In the record-keeping context, metadata is divided into two types: descriptive metadata and administrative metadata.

Descriptive metadata is generally used for describing or indexing the content of an electronic file. The Dublin Core is recognized as the most commonly used structure for presenting metadata, and the development of this standard and other descriptive metadata standards is driven by the need to support Internet commerce or other business applications. Dublin Core does contain elements that support retention of some but not all of contextual information necessary for effective record keeping.

Administrative metadata addresses more of the contextual information necessary to understand the accuracy and authenticity of the content. It also can facilitate management and preservation of the electronic file over time. Administrative metadata can document such attributes as document version, software and hardware requirements, location and availability of other metadata such as software documentation, location and availability of backup files, and migration history. Establishing and implementing administrative metadata standards would greatly improve the prospects for electronic record preservation in the future.

Electronic Resources & Libraries (ER&L)

Jesse Koennecke

Cornell University Library, Cornell University College of Arts and Sciences, Ithaca, New York, U.S.A.

Abstract

The annual Electronic Resources & Libraries conference (ER&L) was first held in 2006 to bring people together to focus directly on the trends, workflows, and technologies involved in managing electronic resources within the library community. Attendees gather, both in person and online, to find common ground, learn, and have an impact on their profession.

INTRODUCTION

The Electronic Resources & Libraries conference, or ER&L, is an annual international library conference focused on trends, workflows, and technologies involved in the management, maintenance, and accessibility of electronic resources in libraries. ER&L's stated mission and purpose, as found on <http://electroniclibrarian.org/about/>, focus on the need for communication and collaboration to enable individuals that deal with electronic resources to keep up in a quickly evolving environment. With these in mind, attendees gather annually both in person and online to learn from one another, make connections, and develop a better understanding of how to go about their work.

Mission: ER&L facilitates the communication and collaboration for information professionals around issues related to managing electronic resources in the digital world.

Purpose: The goal of the ER&L conference is to bring together information professionals from libraries and related industries to improve the way we collect, manage, maintain, and make accessible electronic resources in an ever-changing online environment. We do this once a year at an in-person conference. In addition, sessions are recorded and made available in an online conference. ER&L allows for cross-pollination of ideas across fields of librarianship not often brought together in traditional public services or technical services conferences.

HISTORY AND GROWTH

ER&L was first conceived by Bonnie Tijerina, a librarian at the Georgia Institute of Technology (Georgia Tech) at the time. Tijerina attended a conference where someone presented on a survey they conducted with a new area of the profession called e-resources librarianship. The results of the survey indicated people working primarily with electronic resources felt isolated and overwhelmed. Survey respondents said their colleagues didn't understand what

they did and that there was a lack of standard practices across library vendors. In an e-mail interview, Tijerina recalled, "While I attended the session I thought that if a lot of the librarians from across the country could get together, they could build community, share best practices, and work closely with vendors to communicate the needs of the library community." She put out a call to the broader community, asking a few questions about what conferences cover e-resources professional development and if a new conference was needed. Getting a lot of positive responses, as well as volunteers to help, she set about organizing a conference.

What was to become the first annual ER&L was held March 23–26, 2006, in Atlanta, Georgia, on the Georgia Tech campus. Featuring two keynote speakers and 33 sessions spread across 10 tracks, the conference drew approximately 100 attendees. The opening keynote by Robert McDonald, associate director of Libraries for Technology & Research at Florida State University at the time, set a tone that has continued to drive the forward thinking nature of the ER&L conference since. He applied the concept of Internet 2.0 to libraries, using the term Library 2.0 to illustrate how library systems and services could develop in the coming years. The presentation tracks from the first ER&L reflected the broad topics that staff working with electronic resources were wrestling with, mostly on their own.

First ER&L Conference Tracks

Organizational Change
Access
Electronic Resource Management
Partnerships
Consortia
Usage Data
Workflow
Licensing
Resources
Technology

From that first event to celebrating its 10th annual in 2015, ER&L has changed location several times and grown considerably. In addition, the organizers and volunteers have continued to adjust their plans to ensure the conference evolves and continues to meet its mission and purpose in the changing world of electronic resources.

ER&L remained in Atlanta then moved to Los Angeles in 2009. As of 2010, ER&L has had a regular home in the early spring on the University of Texas at Austin campus.

Throughout this time, Tijerina has continued to serve as the conference coordinator, assisted by numerous regular volunteers. Among these volunteers are several that have been key to ER&L since the beginning. Elizabeth Winter (Georgia Tech) has been the chair of program planning committee, managing the process of reviewing and finalizing the extensive set of presentations that are at the primary content of ER&L. Jill Emery (Portland State University) has filled many different roles including program planning, engaging sponsors, communication, and social media. As of 2015, there are dozens of individuals involved in planning the conference and dozens more that volunteer on-site to help keep everything running smoothly.

Since 2009, Tijerina has relied on the advice and business skills of her sister, Sandy Tijerina, who in 2012 became ER&L's first and only full-time paid employee. As sponsorship and communications director, Sandy handles the logistics for the conference planning as well as the physical conference itself. She also coordinates the vendor exhibits and sponsorship activities that are a major part of sustaining ER&L.

Attendance has grown steadily from those initial 100 in 2006. By 2010, the number had reached 400, then up to 650 on-site in 2015. Although the vast majority of attendees come from the United States, a growing number are travelling from abroad with representation from 22 countries across 6 continents.

Beginning in 2011, ER&L introduced an online conference option, recording and streaming select sessions to an online audience. Since 2014, the online conference has streamed most of the live sessions and keynote speakers. This has allowed participation in the conference to grow further, enabling people to attend the conference after the attendance cap has been reached or if they are unable to travel to Austin in person. In addition to the on-site attendees in 2015, another estimated 450 joined via the online option. A group rate makes it more affordable for several individuals from an institution to take advantage of the online conference. Presenters, in-person attendees who pay to add online access, and all online attendees are able to access the recorded sessions to cover any that they missed or wish to review.

In addition to examples like the online conference, ER&L continues to innovate to keep ahead of trends and to push boundaries of what people who work with e-resources consider important to their work and

profession. This can be seen in the topics that the keynote speakers address, in the focus of the presentation sessions in any given year, and in the nature of the related events (see the following text) that have emerged out of ER&L.

Keynote speakers over the history of ER&L have been invited specifically to provide insight into the broader world of libraries and beyond. A few examples from past ER&L conferences illustrate how the keynotes can serve as bridges to topics that are not traditionally associated directly with electronic resource management in libraries. In 2013, Michael Eisenberg, dean emeritus of the Information School at the University of Washington, presented "Listening to Users: What the 'Google Generation' Says About Using Library & Information Collections, Services, and Systems in the Digital Age," sharing how young users do research and what they think of the library. That same year, Rachel Frick, director of the Digital Library Federation (DLF) at the time, gave an inspirational talk titled "The Courage of Our Connections: thoughts on professional identities, organizational affiliations and common communities," about the increased role librarians can play in the networked world. In her 2014 talk "Freeing Knowledge: A Values Proposition," Barbara Fister, a librarian at Gustavus Adolphus College and blogger for *Inside Higher Ed* (<https://www.insidehighered.com/>), spoke about library values, the open movement, and how libraries could lead in developing an open network. These and other ER&L keynote addresses are available to the public on the ER&L website.

The selection of concurrent presentation sessions and longer workshops changes from year to year, as new topics emerge in the world of electronic resources. ER&L's program planning committee sorts through submissions and hosts an online community voting process to finalize the slate of presentations. This allows the community to have a direct impact on the upcoming conference to make it as relevant and timely as possible. These sessions are supplemented by informal activities like lightning talks and roundtables to provide opportunities for people to actively discuss ideas that may not have been previously proposed.

Throughout its first 10 years, the organizers for ER&L have actively worked to increase the social aspects of the conference. In addition to being a useful networking opportunity for people working with electronic resources and library vendors, ER&L includes a number of social and entertainment opportunities to give attendees a chance to connect outside of conference presentations. Early on, these included organized dining events, tours, networking sessions, and receptions. Recently, organizers have held a Battledocks competition and a gaming night.

ER&L had benefited from sponsorship since its inception. Growing from 11 sponsors in 2006 to 56 in 2015, the conference draws interest and support from publishers, library content and service vendors, and related organizations. Sponsors support ER&L by hosting luncheons and

receptions, providing scholarships, and helping to cover the costs of the conference services such as A/V technology.

ER&L TODAY

Planning and organizing ER&L occurs throughout the year, coordinated by both Bonnie and Sandy Tijerina. They are in communication regularly with the host site, sponsors, and volunteers during the lead up to the actual conference. As of the 2016 conference, the planning committee consists of the following subcommittees and functions: program planning, fellowship, fun and games, grants, sponsorship, social media, web, workshop, and local logistics.

The typical calendar for conference planning begins 6–8 months before the conference and includes

- Keynote speakers identified and invited
- Sponsors recruited on an ongoing basis
- Call for workshops in early fall
- Call for concurrent session proposals in the fall
- Community voting several months before the conference
- Notifications of acceptance by late fall or early winter
- Developing the official schedule
- Conference typically held in late March/early April

As with many conferences, individual sessions are assigned to a track to help attendees identify a focused group of session to attend. The focus of the conference tracks change over time as the nature of the library electronic resource world changes. The tracks from 2016 conference website are as follows:

Managing e-resources and licensing: Managing electronic resources is a challenge, whether you're new to it or have been engaged in it for years. Which systems and tools can be used to manage electronic resources more effectively? What kinds of challenges are new formats posing? How are we rearranging our workflows to find solutions to e-resources problems? What can we achieve through more thoughtful licensing? How can standards and best practices assist our efforts?

Collection development and assessment: How do we demonstrate value to our larger organizations? Are our collection and analytic processes as efficient as they could be? Can collecting data be easier? How can we best analyze what we collect?

Organizational strategies: Our organizations regularly evolve due to changes in leadership and strategic vision, budget constraints, user needs, and the simple fact that so many of our resources are now online. All of these impact the way we manage e-resources. What type of leadership has helped create positive change? What are some

examples of beneficial organizational shift and improved communication? Where are there opportunities for internal collaboration? Where do we still need to open up communications?

External relationships: In the digital world, libraries don't stand alone. They work closely with consortia, vendors, other libraries, and intermediaries. Are all these relationships working? Are we getting the most out of our relationships with other organizations or groups? How can we improve our external relationships?

User experience: Libraries exist in large part to support our users. How can we better serve our user populations? What kinds of communications will help us reach them when so much is competing for their attention? How can we demonstrate to users the value of libraries and create a better user experience?

Scholarly communication: How do we deal with new models of scholarship that are emerging? How do we accommodate new forms of content? What can we do to facilitate knowledge sharing and access?

Library as publisher: What role can the library play in the creation and distribution of the products of scholarship and creativity?

Emerging technologies and trends: So much of what we do in libraries today is driven by technology, and so many of the problems we face can be solved, at least in part, by employing or developing new technologies. How are current technologies being used? What emerging technologies are on the horizon? How can we employ them effectively to meet the information needs of the library, internally and externally?

RELATED EVENTS

Library Idea Drop House—(<http://electroniclibrarian.org/ideadrop/>): Starting in 2012, Tijerina hosted the Library #IdeaDrop House, inviting speakers from the SXSW Interactive Conference to discuss topics of interest to libraries in a small, relaxed setting. Partnering with regular ER&L sponsor, ProQuest, the IdeaDrop House has continued annually to offer conversations about libraries, data, privacy, and other topics.

UX Day: Andrea Resmini, information architect and a teacher and researcher at Jönköping University in Sweden, was an ER&L keynote speaker in 2012. He spoke about cross-channel experience for our users and how the information and services they utilize from a library's digital space is one of many facets of the larger information landscape they interact with in their daily lives. This concept led to a user experience or UX Day at ER&L 2014 with the goal, as expressed on its website (<http://electroniclibrarian.org/erlplus/uxday/>), “to educate and expose librarians and other information professionals to colleagues working on user experience, discovery, usage and usability projects in libraries and professionals working

in user experience outside of libraries.” The concept of UX Day was to concentrate on user experience–related sessions, speakers, and workshops. Invited presenters included Susie Herbstritt, senior interaction designer for Dell; Brian Taylor, senior user experience researcher and designer for Dell; and Matt Franks, professor at the Austin Center for Design and product owner and lead interaction designer at MyEdu. UX for Good founders, Jason Ulaszek and Jeff Leitner, and TEDxAustin Executive Producer Nancy Giordano led a hands-on workshop. ER&L attendees could attend the UX Day and individuals could register separately to join the UX Day on its own.

Designing for Digital: The success of UX Day led Tijerina to start Designing for Digital (<http://www.designingfordigital.com/>), a separate conference immediately following ER&L in 2015. Designing for Digital is held in the same location as ER&L, allowing interested people to attend both without additional travel, while it provides a robust enough conference experience to draw additional attendees that are specifically working on user experience, discovery, design, and usability projects inside and outside of libraries. Tijerina is joined by UX designer, Judy Siegel, to coordinate Designing for Digital.

Library Publishing Unconference: An example of how ER&L fosters innovative ideas, ER&L hosted a Library Publishing Unconference in 2013. A regular attendee, Amy Buckland (McGill University), proposed the idea and was encouraged to go ahead and organize it with the support of ER&L. The announcement for the Unconference encouraged attendees to come with their own questions, ideas, and enthusiasm to discuss issues around open access publishing, how the library can support and/or supplement the university press, and how to help faculty comply with open access guidelines.

AWARDS AND SCHOLARSHIPS

DLF/CLIR + ER&L Cross-Pollinator Travel Award (2013–): Cosponsored by ER&L and the DLF, this grant

was introduced to provide an opportunity to a library professional who might not normally attend ER&L, but whose work might align well with the goals of ER&L. As a cross-pollinator, the grantees bring perspectives from the DLF, connecting ideas from the broader library profession to the core ER&L mission. The travel grant includes a conference registration, air travel costs, and housing.

Taylor & Francis Group Student Travel Grant (2013–): Taylor & Francis Group has offered an annual scholarship for two aspiring e-resource librarians to support their travel, registration, and lodging at the ER&L conference. This scholarship was introduced in an effort to promote and increase opportunities for students to attend the conference. Applicants must be currently enrolled students from anywhere in the world. They are required to answer questions in writing about how ER&L can help them meet their professional goals.

CONCLUSION

ER&L arose in response to a vacuum of resources and support for those who manage electronic resources in libraries. Over its first 10 years, the conference and community has filled this gap and innovated to keep at the forefront of this continually changing area of the field. ER&L offers professional growth opportunities for new librarians and information professionals, those who are new to electronic resources, and to those who have been involved for many years. It was founded on the principle that by coming together as a community, ER&L participants can find common ground with each other to learn and have an impact on their profession.

ER&L can be found on

Encoded Archival Description

Daniel Pitti

Alderman Library, Institute for Advanced Technology in the Humanities, University of Virginia, Charlottesville, Virginia, U.S.A.

Michael Rush

Beinecke Rare Book and Manuscript Library, Yale University, New Haven, Connecticut, U.S.A.

Abstract

Encoded Archival Description (EAD) is an international standard based on Extensible Markup Language (XML) for encoding descriptions of archival records. People living their lives as individuals, as members of families, and as members of corporate bodies create and assemble records that serve as instruments for carrying out or documenting the performance of activities. Based on the archival principles of *respect des fonds* (or provenance) and original order, archivists traditionally have treated all of the records created and assembled by one individual, family, or corporate body as a collection or *fonds*. Archivists describe records as an essential part of their responsibility for preserving and facilitating access to and use of archives. Archival description provides information essential for establishing the authenticity and completeness of *fonds* and serves effective administration, discovery, access, and understanding of records. Traditionally, archivists have described each *fonds* hierarchically in a single apparatus commonly called a finding aid. Until the advent of computing, finding aids were typically in printed form. In the 1990s, archivists created EAD, an encoding standard for archival description that made it possible to derive online and print finding aids from the same structured data. EAD is based technologically on XML and intellectually on *General International Standard Archival Description (ISAD(G))*, a descriptive framework developed by the International Council of Archives (ICA). The third version of the standard, EAD3, will be released in 2015 and will continue to develop in the future. Future changes to EAD will be influenced by ICA descriptive standards, in particular the conceptual model and ontology for archival description to be developed by the Experts Group on Archival Description, and related encoding standards. This entry is organized into six sections: introduction, archival records, archival description, EAD, history, and future.

INTRODUCTION

Encoded Archival Description (EAD) is an international standard for encoding descriptions of archival records. An individual archival description is commonly called a finding aid, archival guide, handlist, inventory, or register. Though these terms cover a wide variety of apparatus, they most commonly refer to a hierarchical description of records that share a common origin or provenance. A collection of records sharing a common provenance is called a *fonds* or simply a collection. The hierarchical description begins with a description of all records in a *fonds* and then proceeds to a description of components, typically identified by the activity or function that they document (for example, correspondence or minutes of meetings). These components and components of components, and so on, may be analyzed and described, with the hierarchical analysis and description terminating in the description of a file or an item. The depth of analysis is determined by both intellectual criteria and available time and resources.

EAD is a standard for communicating archival descriptions and is not itself a standard for the content of the

descriptions. The general standard for descriptive content is *General International Standard Archival Description (ISAD(G))*,^[1] developed by the International Council on Archives (ICA). *ISAD(G)* provides general guidance on the composition of archival descriptions and serves as the basis of national standards such as the Society of American Archivists' *Describing Archives: A Content Standard (DACS)*.^[2] As a communication standard, EAD has a number of interrelated purposes. In conjunction with complementary content standards, it is intended to promote the regularization of description in order that the data are consistent and readily understood by users across archives. Regularized description and encoding enables intelligent searching, rendering, navigation, access, and use of archival materials. And since EAD is based on Extensible Markup Language (XML), a widely used and supported standard for developing encoding schemas, it provides reasonable assurance that the data will endure changes in hardware and software. Finally, standardized description enables the repurposing of archival description, including its eventual migration into successor encodings, and aggregation of descriptions across repositories to provide union access to distributed archival resources.

The Society of American Archivists (SAA) is responsible for the maintenance and development of EAD and the Library of Congress hosts the standard and official documentation. Within SAA, the Technical Subcommittee for Encoded Archival Description (TS-EAD) is responsible for the intellectual and technical content of the standard. The members of the Technical Subcommittee reflect the international nature of the standard, with members from the United Kingdom, Germany, France, the Netherlands, Sweden, Italy, Canada, and the United States.

The standard was first released in 1998. It was revised in 2002 and a third version—EAD3—will be released in 2015. The first two versions of the standard were in the form of an XML Document Type Definition (DTD) with an accompanying Tag Library. In 2007, EAD was released in the form of a schema, an alternative syntax for defining the standard. EAD3 will be maintained as a Relax NG schema but will also be available as a W3C schema and a DTD. The schemas and DTD provide the formal semantic and structural requirements of the standard and are used by software to validate encoded instances of archival descriptions. The Tag Library provides guidance on the use of the elements and attributes prescribed in the schemas and DTD and used to encode descriptive data.

ARCHIVAL RECORDS

Archival records are created and assembled by people living their lives as individuals, as members of families, and as members of corporate bodies. The creation of records is typically not the objective of the activities, but rather the records serve as instruments for carrying out or documenting the performance of activities. Archival records thus document people and organizations performing activities or functions, and as such, may serve as legal evidence and historical evidence. By contrast, the books and journals that constitute the bulk of most library collections are the objectives of the activities that created them. To illustrate this difference, it is useful to look at the creation of an encyclopedia.

At the beginning, the editors have the objective of publishing an encyclopedia. They correspond with a publisher with the proposal. Or perhaps the publisher conceives of the encyclopedia and contacts one or more editors. In either case, through a series of exchanges the publisher and editors negotiate the scope and content of the encyclopedia, the form or forms of publication, financial arrangements, methods for soliciting authors and editing entries, and so on. In turn authors for entries are solicited and a series of exchanges take place between the editors, authors, and publisher. Various agreements are formally made and signed. The authors are given formal instructions and deadlines. The authors create and submit drafts of articles to the editors, and after another series of exchanges, the authors submit entries to the publisher for publication. At each

stage, the participants in the creation and publication of the encyclopedia generate and maintain copies of the correspondence, agreements, instructions, drafts, financial transactions, and so forth. All of these documents serve the dual purpose of creating and publishing the encyclopedia and documenting the activities that lead to its publication. Each document is not an objective in itself but an instrument by which the objective is realized.

The participants' involvement in the creation of the encyclopedia constitutes only one set of activities over the course of their existence. The authors and the editors have both professional and personal lives. The publishing company publishes more than one book. Each participant generates and accumulates records over the course of a lifetime or existence. Many of these records will be kept for legal reasons, such as financial accounting and reporting, as proof of responsibilities performed, or perhaps self-consciously as records documenting a life or the history of a business. All of the records generated or accumulated by an individual, family, or corporate body, collectively serve as documentation of the life of the individual, or the history of the family or organization. When they are assembled and preserved, they are archival records. Each collection of records generated and accumulated by one individual, family, or organization is called a *fonds*. The items in a *fonds* share a common origin or provenance.

When considered individually, records frequently make little sense and thus have little value. It is only when individual records are considered in context, in relation to other records that document a network of interrelated transactions or series of transactions carrying out a particular function, that they can be understood. In this way, archival records are quite different from books and journals, as the latter are intended to function independently. This statement ignores the issue of intertextuality, which is beyond the scope of present considerations. Archival records are by and large unique. In this respect, archival records again differ fundamentally from books. Books and journals are not unique, at least not in ways that would be of interest to most users. Typically, books and journals exist in many copies, and any one copy will serve as well as any other.

Archival records are varied in both content and format, and the number of items in any given *fonds* may be quite large. While many records are exclusively or primarily textual, these may be in the form of handwritten, typed, printed, or digital. The content may be minutes of a meeting, a marriage license, receipts, a report card, correspondence, and so on. Sound, photographic, and audiovisual records may be in any format used for recording each of these forms. Content again will be varied, depending upon the context and the purpose of the recording. Maps, similar to textual records, may be hand-drawn, printed, or in digital form, as images, graphics, or as geographic information system (GIS) data. While a *fonds* may contain

exclusively one form or content, it is more likely, in particular with respect to personal and family records, that both the form and content of the records will be diverse. In addition to a variety of form and content, the number of items in any given *fonds* may be quite large. The administrative records of Tom Bradley, who served as the mayor of Los Angeles from 1973 to 1993, are stored in 4253 boxes occupying 2101.5 linear feet of shelf space.^[3]

ARCHIVAL DESCRIPTION

Archival description reflects the nature of archival records and the mission of the archival institutions into which their care and management is placed. Like museums and libraries, archives have a responsibility to remember on behalf of others. Preservation is the first essential responsibility, for without the physical preservation, memory fails. Equally important though is a description of archival records that provides information essential for establishing their authenticity and completeness and serves effective administration, discovery, access, and understanding. Archival preservation and description make the remembering as trustworthy, reliable, and thorough as possible. To serve these objectives, archival description has traditionally focused on the *fonds* as the fundamental unit of description rather than the individual items, as is the common practice in libraries and museums. While there is an obvious savings of time and effort in collection-level description, this descriptive practice is based on the nature of archival records and the objectives to be served.

Archival description rests on two fundamental principles, *respect des fonds* and principle of original order. *Respect des fonds* is frequently also called the principle of provenance. While understanding of this principle has undergone ongoing interpretation since its articulation by French archivists in the early nineteenth century, its fundamental meaning has remained unchanged. Archivists must honor the origin and integrity of records generated or accumulated by an individual, family, or corporate body. The records generated or accumulated by a single source are intricately related to that source, whether it is a corporate body performing the functions with which it is charged or an individual pursuing personal and occupational activities. Given this intimate relationship, records cannot be understood apart from their origin. From this follows the archival practice of treating all records with a common provenance as a group.

The principle of original order addresses the arrangement of the archival records. The concept of original order is frequently conflated with the physical arrangement of records as received by the archive, though it is better understood as an intellectual arrangement that reflects the purpose and use of the records by the creating entity.^[4] Commonly, particularly with records deriving from and maintained within a corporate body (such as a government

agency or business), records have been arranged and maintained to support the functions and related transactions performed by the body. In such cases, the physical order reflects the purpose and use of the records. It is quite common, though, that the arrangement of the records as received by the archive does not reflect a discernable order, and it is incumbent on the archivist to analyze and arrange the records to reflect their understood purpose and use.

Based on the application of the principle of *respect des fonds* and the principle of original order, archivists maintain and describe all records in a *fonds* together, physically arranged to reflect the original order. A description of a *fonds* begins with a description of the whole and, through a progressive, hierarchical analysis, describes components of the whole based on a shared characteristic or characteristics, which may in turn be analyzed into components and described. The analysis and description can progress to the item level, though frequently do not. Each level of description has a formal designation based on the nature of the shared characteristics that identify them as a coherent group: *fonds*, series, file, and item. Series and files may have intervening levels. The depth of the description is based on both intellectual and economic considerations. While it may seem counterintuitive, excessive analysis and description may hinder rather than facilitate the discovery, identification, and use of archival records, a phenomenon known as “getting lost in the details.”

Archival hierarchical analytic or multilevel description is shaped in part on two rules. First, the description of a component at any given level applies exclusively to that component (including its hierarchical descendants). Second, the description of a given component inherits the description of its parent, including any description the parent inherits from its parent, and so on up to the top level. A number of distinctive features follow from these two rules. Typical finding aids begin at the top level with several descriptive components, many of which may comprise detailed prose. At each successive level, the number of descriptive components and the amount of data supplied decrease. It is quite typical for the top level of description to provide lengthy narrative description, while an item-level description may be no more than a title or a date. Viewed from the perspective of the entire archival description, though, the item inherits all of the description back to the top level.

A third rule governing archival description dictates that all components of description are available at each level of description. This rule addresses the fact that individual archival collections are each unique, as they each reflect the lives and activities of individuals, families, or corporate bodies in particular places and times. They also vary greatly in the forms and quantity of records. In principle, all elements of description may be appropriate at any level of description. In practice, though, given inheritance and progression from general to specific, both the elements and quantity of description typically follow common patterns.

In a typical description, the top- or *fonds*-level contains information about the entire collection. The following information is typically given succinctly:

- Identifier or designation that is unique within the repository
- Title of the *fonds*
- Date range giving the earliest and latest dates of creation, frequently with a second range for the dates within which the bulk of the materials was created
- Provenance or creator information
- Extent of the collection, typically given in linear units of shelf space occupied and number of boxes
- Repository holding the collection
- Language or languages represented in the content

Information generally provided in brief text form at the top level includes the following:

- Restrictions on physical access to the materials
- Copyright restrictions
- Scope and content or biography/administrative history abstract
- Preferred form of citation
- Processing and acquisitions information
- Related and separated materials

Finally, the following information is commonly given in expansive text form:

- Biographical/administration history
- Scope and content
- Overview of the arrangement of the materials

The detailed analysis of the *fonds* into components follows. The form of this analysis varies considerably from description to description, and sometimes within a single description from component to component. Some patterns of analysis, though, are prevalent: *Fonds*-series-file, *fonds*-series-subseries-file, *fonds*-series-file-item, and *fonds*-series-subseries-file-item. The pattern of the hierarchical analysis is not prescribed but is determined by the judgment of the archivists analyzing and processing the collection.

Series and subseries descriptions frequently include the following information:

- Title
- Dates range giving the earliest and latest dates of creation
- Extent
- Scope and content
- Arrangement

File or item information commonly includes the following:

- Title
- Date or date range
- Container information

Container information or storage location is provided at the terminal node of description, which corresponds to the most specific intellectual unit that can be requested for use. In the scenario described earlier, this may be an item or file; though when the description terminates at the series or subseries level, container information will be provided at these levels.

ENCODED ARCHIVAL DESCRIPTION

Technical Foundation

Traditionally, archival description was typescript and then later printed using word processors and to a lesser extent, database software. With the emergence of markup technologies in the middle to late 1980s, it became possible to create machine-readable findings that were descriptively encoded and thereby supported a much broader range of functional possibilities. Standard Generalized Markup Language (SGML) was first issued as a formal standard in 1986 by the International Standards Organization (ISO). In the early 1990s, the Hypertext Transfer Protocol (HTTP) and an accompanying document encoding standard, Hypertext Markup Language (HTML), became the foundation of the rapidly emerging World Wide Web (WWW). The success of HTTP and HTML gave rise to the World Wide Web Consortium (W3C), which turned its attention to the development of standards. While remarkably successful, HTML was insufficient for secure, flexible, semantically rich exchange of information, and SGML, though supporting flexible, semantically rich exchange, was difficult to process. As an alternative to both SGML and HTML, the W3C developed XML, releasing version 1.0 in 1998. Among the key features of both SGML and XML was the ability to develop community-based rules or schemas to govern the encoding of specific kinds of documents, employing a semantics that reflected the nature of the document and the professional language of the community. The archival community was one of the first to employ XML.

The archivists developing EAD chose XML as the best available technology for developing a communication standard for archival description for a number of reasons. Markup and database technologies are the two prevailing techniques for representing textual data in forms that support complex, multipurpose processing. While they have some overlapping functionalities, each is optimized to support specific and distinct kinds of data. Markup technologies support traditional documents, such as books, journals, and journal articles, where the order of components and unbounded component hierarchies are prevalent. Database technologies support information with complex many-to-many relations, and the particular order of data elements has minimal if any significance. Archival description can best be characterized as occupying a

middle ground, having structurally different data components that map well to one or the other technology. For the purposes of communicating information, as opposed to its creation and maintenance, XML is the superior representation, as it will accommodate native XML data and data derived from databases.

In addition to its representational capability, XML also offers other attractive features. Since its release in 1998, XML has been widely adopted and supported, not only by the original document community where SGML had had reasonably good success, but also by the database development community. As a widely used and supported standard for developing encoding schemas, XML provides reasonable assurance that the data will endure changes in hardware and software, an essential concern because digital data are absolutely dependent on computers for retrieval and rendering into human readable form. The semantically and structurally rich descriptive encoding made possible by XML also enables multiple uses of the data: a wide range of alternative renderings for onscreen presentation and printing, in-depth and descriptive component-specific indexing and retrieval, and, when a successor to XML emerges, migration into a successor digital representation.

There are several apparatus for a defining rule-based encoding for a particular class or kind of documents, including DTD, ISO Relax NG Schema, and W3C Schema. EAD exists in all three forms. The semantics and structure of each are the same, although the schemas add compliance with other XML and descriptive markup schemas, constraints on some data values, and the option to embed XML objects defined according to external rules.

Semantics and Structure: Top Level

In EAD3, the new version to be released in 2015, EAD (<ead>) comprises two main sections: Control (<control>) and Archival Description (<archdesc>). The <archdesc> contains the archival description itself, while the <control> contains control information about the description. Both <control> and <archdesc> are required. For detailed information on the semantics and structure of EAD versions 1.0 and 2002, see the Society of American Archivists, and Library of Congress^[5] and Ruth.^[6] When it is published, the EAD3 Tag Library will be hosted at the Library of Congress.

While an EAD document provides information describing and documenting archival materials, it is itself a resource that must be maintained and managed. The <control> section contains information that facilitates control of the resource. It contains the following sections:

Record Identifier (<recordid>): a unique designation for identifying and tracking the EAD instance.

Other Record Identifier (<otherrecordid>): an alternate designation for identifying and tracking the EAD instance.

Representation (<representation>): a link to a deliverable version of the description.

File Description (<filedesc>): title, edition, publication, series, and notes describing the description.

Maintenance Status (<maintenancestatus>): enumerated values indicating the drafting status of the EAD instance.

Publication Status (<publicationstatus>): enumerated values indicating the publication status of the EAD instance.

Maintenance Agency (<maintenanceagency>): the institution responsible for the creation, maintenance, or dissemination of the Encoded Archival Context—Corporate bodies, Persons, and Families (EAC-CPF) instance.

Language Declaration (<languagedeclaration>): declaration of the language used in the EAD instance.

Convention Declaration (<conventiondeclaration>): declaration of the rules or conventions, including authorized controlled vocabularies and thesauri, applied in creating the EAD instance.

Local Type Declaration (<localtypedecclaration>): declaration of any local conventions used in the local type attribute in the EAD instance.

Local Control (<localcontrol>): additional control entries necessary to accommodate local practice.

Maintenance History (<maintenancehistory>): information on the history of the creation and maintenance of the EAD instance.

Sources (<sources>): the sources used for the description of the records in the EAD instance.

Of these sections, <recordid>, <filedesc>, <maintenancestatus>, <maintenanceagency>, and <maintenancehistory> are required.

The section dedicated to an archival description is <archdesc>. The <archdesc> is probably best understood as representing the logical semantics and structure of archival description, with additional semantics and structure that facilitate navigable and intelligible rendering for those seeking archival records. These additional structures enable labeling sections or descriptive components and rendering them in forms that are readily understood. An example of the former is Head (<head>), which enables the archivist to supply section titles, and an example of the latter is Paragraph (<p>), which enables rendering of prose description. The primary focus of <archdesc>, though, is the hierarchical description itself.

The first component of the archival description is Descriptive Identification (<did>). The <did> is intended to succinctly provide all of the information

necessary to uniquely identify the collection and make a competent first-pass judgment of its relevancy. The information is succinctly stated and collocated in order to function as a summary surrogate for the complete description, in particular in retrieval sets in union archival description systems (such as those used by state and regional consortia, and archival gateways). Archivists have identified the following descriptive elements to support these objectives:

Unit Identifier (<unitid>): unique identifier of the *fonds*, including a national identifier and repository identifier.

Unit Title (<unittitle>): title of the *fonds*.

Unit Date (<unitdate>) or Unit Date Structured (<unitdatestructured>): date range of the earliest and latest creation, frequently with a second range for the dates within which the bulk of the materials was created.

Origination (<origination>): Provenance or creator information.

Physical Description (<physdesc>) or Physical Description Structured (<physdescstructured>): description usually of the extent of the materials described, either in terms of the space occupied (e.g. linear feet), carriers (e.g. number of boxes), or material types (e.g. a count of photographs).

Repository (<repository>): archival institution holding the collection.

Language of the Materials (<langmaterial>): Languages or scripts represented in the content, with languages provided in Language (<language>) and scripts provided in Script (<script>).

Abstract (<abstract>): summary of either or both the scope and content, or biography or administrative history.

Following the summary description of the *fonds*, several components already described in summary form are described in more detail. In addition, some new descriptive elements that are not considered essential to the objectives of the summary description but are essential or at least useful for fully understanding and using the collections are provided. Expanded descriptions are commonly provided for Scope and Content (<scopecontent>) and Biography or History (<bioghist>), both of which may have been provided in summarized form in the <abstract> in the <did>. Further information may be provided in the following descriptive components:

Arrangement (<arrangement>): information on the intellectual analysis and arrangement of the records, reflecting, in principle, the original order

and the hierarchical analysis reflected in the description.

Access Restrictions (<accessrestrict>): information concerning limitations on physical access to the records because of privacy, agreements with donors, or other reasons.

Use Restrictions (<userrestrict>): information concerning copyright restrictions.

Acquisition Information (<acqinfo>): information on the immediate source of the records and the circumstances of the acquisition.

Controlled Access (<controlaccess>): controlled personal name, family name, corporate name subject, genre or form, function or activity, geographic, title, and other headings under authority control.

Preferred Citation (<prefercite>): information on the preferred form of citation of the records in referencing or citing publications.

Processing Information (<processinfo>): information on archival record processing activities applied to the records such as accessioning, describing, preserving, and storing.

Related Material (<relatedmaterial>): information, usually in the form of a citation, on intellectually related records (though not related by provenance).

Separated Material (<separatedmaterial>): information, usually in the form of a citation, on publications and artifacts in a collection, or archival records that have been separated from the *fonds*, frequently for curatorial reasons.

Accruals (<accruals>): information about anticipated additions to the materials, including (when available) information indicating the quantity and frequency of additions.

Several additional descriptive components are available. This additional information is provided when it is appropriate and available. When copies of the records, such as microfilm copies or digital facsimiles are available, this is typically noted. The corollary is also true, that is, in the description of copies of archival records, information about the originals is provided. If there is more than one description of a *fonds*, each description will reference the alternative description. For example, predominately French-language *fonds* may be held by an institution that prepares descriptions in English. A French translation of the original English description would function as an alternative finding aid.

EAD attempts to be comprehensive in accommodating accepted components of archival description. Due to the nature and complexity of archival records and the *fonds* within which they are interrelated, descriptive information deemed essential or at least useful may not be

accommodated within an existing element. EAD accommodates such information with the Other Descriptive Data (<odd>). It is similar to the use of a general note in bibliographic description.

Semantics and Structure: Hierarchical Analysis

The EAD apparatus used in the hierarchical analysis is the Description of Subordinate Components (<dsc>). The key element within the <dsc> is the Component, which comes in two forms, simple and enumerated. To enable hierarchical description, each Component is recursive, which is to say, it is available within itself. The simple form is called <c>, and the enumerated form is called <c01>, <c02>, through <c12>. The major difference between the two forms is that the <c> permits unlimited recursion or depth of analysis, and the enumerated limits depth of analysis to 12 levels. Because more than 12 levels of analysis is rare, choosing which form of the Component to use is primarily a decision based on ease of use and processing, usually influenced by the software chosen for processing.

Each <c> or <c01> through <c12> contains all of the descriptive components available in the <archdesc>, beginning with the <did>. This availability reflects a rule governing archival description described earlier, that all components of description are available at each level of descriptive analysis. Thus all of the <did> contained elements are available, as are <scopecontent>, <arrangement>, and so on. While all of the components are available throughout the hierarchy, because of the inheritance of description both the number of elements employed and the quantity of description contained in them typically decrease through each descending level of analysis.

In order to understand the way in which the hierarchical analysis unfolds as reflected in the EAD structure, it is useful to translate common patterns of analysis. The following examples exclude the *fonds* description, as it has been covered immediately above.

Fonds-series-file (3 levels including *fonds*)

```
<c01 level="series">
  [description]
  <c02 level="file">
    [description]
  </c02>
</c01>
```

Fonds-series-subseries-file (4 levels including *fonds*)

```
<c01 level="series">
  [description]
  <c02 level="subseries">
    [description]
    <c03 level="file">
```

```
      [description]
    </c03>
  </c02>
</c01>
```

Fonds-series-file-item (2 levels including *fonds*)

```
<c01 level="series">
  [description]
  <c02 level="file">
    [description]
    <c03 level="item">
      [description]
    </c03>
  </c02>
</c01>
```

Fonds-series-subseries-file-item (5 levels including *fonds*)

```
<c01 level="series">
  [description]
  <c02 level="subseries">
    [description]
    <c03 level="file">
      [description]
      <c04 level="item">
        [description]
      </c04>
    </c03>
  </c02>
</c01>
```

It is very important to note that <c01> through <c12> are not to be equated with the level of analysis. The <c01> places the description within a hierarchy but does not itself indicate the level of analysis. The level of analysis is rather indicated through the use of a Level attribute on the tag, for example, <c01 level="series">. Note that in example 1 mentioned earlier, <c02> has the Level attribute value "file," while in example 2, the <c02> has the Level attribute value "subseries." This is further complicated by the fact that even within one series, for example, the Level attribute values of the same subordinate Component may change, depending on the arrangement of the records.

Following the same pattern as the <archdesc>, the first and required descriptive element in each descriptive component is <did>. Typically, each <did>, no matter what the level of analysis (*fonds*, series, subseries, file, item), will contain a <unittitle>, a <unitdate>, or <unitdatestructured>, and often a <physdesc> or <physdescstructured>. For series and subseries analysis, the <did> is generally augmented with a <scopecontent> and an <arrangement>.

When a user identifies records of interest, the archival staff and the user need to know in what box and folder or folders the records will be found (or other container types, as

appropriate to the nature of the records). The organization of records in storage containers has its own inherent physical logic and structure, independent of the intellectual arrangement of the records. EAD privileges the intellectual arrangement in the single hierarchy that XML supports, and thus information on the physical organization and storage is subordinate to the intellectual arrangement. Information about the box and folder or other medium of storage is given in Container (<container>), an element contained in the <did>. Container information is most appropriately supplied at the deepest or terminal components of description. Following this practice, in the hierarchies illustrated earlier, <container> would appear within the <did> in the following component descriptions:

1. <c02 level="file">
2. <c03 level="file">
3. <c03 level="item">
4. <c04 level="item">

Access to archival records can also be facilitated via the Digital Archival Object (<dao>) element. Like <container>, <dao> provides necessary information for the retrieval and delivery of records, but in the form of a link to an online resource rather than a box or folder number.

In order to complete our understanding of how the hierarchical descriptive apparatus works in EAD, it is necessary to understand one additional feature of the use of Component. Not only are the Component elements recursive, they are also repeatable. Thus, at the top level of analytic description, the <c01> is repeated. A *fonds* comprising four series will have a sequence of four <c01>s, one for each series. Within a series, a series containing 12 files will begin with a <c01>, and within it, a sequence of 12 <c02>s, one for each file. While the order of the sequence (arrangement) may not always be significant, in many and perhaps most descriptions it is important, such as, when a sequence of files is arranged chronologically by date of creation or alphabetically by title.

Repeating <c01> components

```
<c01 level="series">
  [description of series 1]
</c01>
<c01 level="series">
  [description of series 2]
</c01>
<c01 level="series">
  [description of series 3]
</c01>
```

HISTORY

Work on an encoding standard for archival description began in 1992 at the University of California, Berkeley.

In the early 1980s, archivists developed the MARC AMC (MAchine-Readable Cataloging for Archives and Manuscript Control) format that enabled archivists to make collection-level summary descriptions available in online catalogs. While representing a major improvement in archival access, the full, detailed descriptions found in finding aids remained available only in printed forms. There was a widespread perception in the archival community that a method for making the full descriptions Internet-accessible was needed. Many archivists experimented with the use of database technologies as a solution. The complex, unbounded hierarchical descriptions found in finding aids, however, were not easily accommodated using database technology. The Berkeley effort was initiated by Timothy Hoyer in the Bancroft Library, who recruited Daniel Pitti to work on the problem. With a grant from the U.S. Department of Education, Pitti developed a prototype SGML DTD based on representative sample finding aids contributed by archivists at collaborating institutions in the United States. The FindAid DTD, as the prototype was called, served to demonstrate the feasibility and utility of using markup technologies, rather than MARC or database technologies, to develop an encoding method that would enable Internet-accessible finding aids.

At the conclusion of the Berkeley project, the Commission on Preservation and Access sponsored a conference in Berkeley to bring together archivists, librarians, and technologists to evaluate the results. With encouragement from the participants at this conference, Pitti applied for and was awarded a Bentley Historical Library fellowship that brought together seven archival description experts, Pitti, and Steve DeRose, a systems designer and developer at Electronic Book Technologies. The description experts were Jackie M. Dooley (University of California, Irvine), Michael J. Fox (Minnesota Historical Society), Steven L. Hensen (Duke University), Kris Kiesling (Harry Ransom Center), Janet E. Ruth (Library of Congress), Sharon Gibbs Thibodeau (National Archives and Records Administration), and Helena Zinkham (Library of Congress). The team met for one week in summer, 1995, in Ann Arbor, MI. Based on experience with the FindAid prototype, the team substantially revised the underlying conceptual model, in part in reference to *ISAD(G)*. The prototype standard that emerged from this meeting was renamed EAD.

Subsequent to the Ann Arbor meeting, the Library of Congress and the SAA agreed to share responsibility for further development and maintenance of the emerging standard. SAA formally charged the EAD Working Group (EADWG) in August 1995 with overseeing the ongoing development of the standard. With support from the Library of Congress National Digital Library Program, Delmas Foundation, and Council on Library Resources (now Council on Library and Information Resources), the EADWG met several times from 1995 to 1998 to further

revise the conceptual model, and review and revise first the alpha and then the beta versions of the EAD DTD and Tag Library. Version 1.0 of the EAD DTD and Tag Library were released in summer 1998. The version 1.0 DTD was compliant with both SGML and XML.

Subsequent to the release of EAD version 1.0, there were developments in both technological and descriptive standards that led the EADWG to begin revising EAD. Released in early 1998 by the W3C, XML was quickly embraced by both developers and users. The availability of software for the editing, validation, and processing of XML made it possible for users of EAD to make a transition from SGML to XML. The ICA also completed its review and revision of *ISAD(G)* in 2000. With funding from the National Historical Publications and Records Commission (NHPRC), the EADWG began revision of EAD in 2000. Based on comments and suggestions solicited from the EAD user community and the second edition of *ISAD(G)*, EAD 2002 was developed and released. Following the release of version 2002, responding to the emergence of schemas as an alternative to DTDs, the EADWG released two schema versions of the 2002 DTD in early 2008, one in the Relax NG Schema syntax and the other in W3C Schema syntax. Funding for this work was again provided by NHPRC.

By 2010, 8 years after the release of EAD 2002, significant developments in both archival description and information technologies made a second revision of EAD necessary, in particular the release of EAC-CPF^[7] in 2010, the development of collection management systems such as Archivists' Toolkit and Archon, and the emergence of Linked Open Data. The SAA Standards Committee charged a new group, the Technical Subcommittee for Encoded Archival Description (TS-EAD) to replace the EAD Working Group, and tasked it to complete a revision of EAD within 5 years. Funding for the revision was provided by the Gladys Krieble Delmas Foundation, the National Endowment for the Humanities, and the Nationaal Archief of the Netherlands. The revision process encompassed four public comment periods and three draft releases, and the resulting version—EAD3—will be released officially in 2015. EAD3 is a significant revision of the standard, with many changes intended to achieve greater conceptual and semantic consistency, make it easier to exchange or incorporate data maintained according to other protocols, and better support multilingual description.

Since its release in 1998, adoption and use of EAD by institutions with archival holdings has increased steadily. While only a few institutions employed EAD in the first year or two after its release, today EAD is used around the world by scores of academic research libraries, business archives, historical societies, museums, national libraries and archives, and other archival repositories. State and regional consortia in the United States have formed to provide union access to the archival holdings of members.

Similar regional, national, and international consortia have formed in Europe and elsewhere. The EAD Tag Library has been translated into Spanish, Greek, Chinese, French, German, Italian, and Russian. Reflecting the internationalization of EAD, the members of the TS-EAD represent seven countries.

FUTURE

Paralleling the ever increasing utility of computer and network technologies, archival descriptive practice has been undergoing a transition from the printed finding aid to an integrated archival description system. This transition is at least in part inspired by the advancements in the technology. Particularly important have been database technologies, in particular relational and object-relational databases, and markup technologies. Each of these technologies is optimized to represent and facilitate the maintenance and use of distinct data structures. Many real world data structures, however, are not wholly of one type or the other, which has required those promoting automation to make difficult compromises when choosing which technology to use. But there are indications that this situation is changing. Many of the major developers of database technologies, responding to real world data structures and needs, are exploring the integration of database and markup technologies. If these efforts are successful, archivists will no longer have to choose between the two technologies and will be able to take advantage of the strengths of each.

In a world dominated by print technologies, archivists have generally employed a single apparatus, the finding aid, to describe all of the records created by a single person, family, or corporate body. For a given *fonds*, the finding aid brought together information describing the creator, the functions performed by the creator, the records that facilitated or documented the performance of the functions, and the archival institution responsible for the records. Since at least the early 1980s, archivists have been discussing “relational” archival systems that enable creating and maintaining each of these fundamental components of description separately and bringing them together dynamically upon user request. Such an approach not only has economic advantages, but also supports more flexible and accurate description, and greatly enhanced access.

The ICA has supported the development of four standards for the components of archival description. The first of these standards, *ISAD(G)*, addresses the description of archival records and was first released in 1993. A second edition was released in 2000. Following *ISAD(G)* was *International Standard Archival Authority Control for Corporate Bodies, Persons, and Families (ISAAR(CPF))* in 1996, with a second edition in 2003.^[8] The third and fourth standards, *International Standard for Describing*

Functions (ISDF)^[9] and *International Standard for the Description of Institutions with Archival Holdings (ISDIAH)*,^[10] were released in 2007 and 2008, respectively. Each of these standards provides a framework for the intellectual content of the four areas of description: records, creators, functions, and repositories. All are intended to function together in a complete archival description. In order to be realized in a dynamic archival description system, though, communication standards for each are necessary.

EAD was originally designed as a communication standard for archival description as represented in finding aids. As such, the four descriptive components were and continue to be interleaved in EAD. Separate, dedicated, and detailed encoding standards for each are necessary, however, to achieve the goal of dynamic and efficient archival description. EAC-CPF is the communication standard for *ISAAR(CPF)*, and preliminary work to develop a communication standard for *ISDF* is under way. A future version of EAC-CPF will likely serve as the communication standard for *ISDIAH*. In addition to communication standards, however, it is necessary to formalize and express in consistent terminology how the components of archival description relate to each other. Toward that end, ICA charged the Experts Group on Archival Description for a term spanning 2012–2016 with the goal of developing a formal conceptual model for archival description and an accompanying ontology.^[11] Future versions of EAD will be heavily influenced by the conceptual model developed by the EGAD and will further integrate with the related communication standards for archival description.

Abstract

Research on the information seeking of engineers over decades has found—despite the many changes in information technologies—on the whole, relatively stable behaviors. This ELIS Classic article from 1993 is written by several people who have been at the forefront of research in this area for some time.

—*ELIS Classic*, from 1993

INTRODUCTION

Engineers are an extraordinarily diverse group of professionals, but an attribute common to all engineers is their use of information. Engineering can be conceptualized as an information processing system that must deal with work-related uncertainty through patterns of technical communications. Throughout the process, data, information, and tacit knowledge are being acquired, produced, transferred, and utilized. (See Entry 2, “Technology Policy and the Technology Base” in *Beyond Spinoff: Military and Commercial Technologies in a Changing World*, by John A. Alic et al. for an in-depth discussion of “tacit” knowledge.) The fact that these data, information, and tacit knowledge deal with hard technologies or may be “physically or hardware encoded”^[1] should not detract from the observation that engineering is fundamentally an information processing activity. The engineer can be viewed as the center of that information processing system. According to Sayer:^[2]

Engineering is a production system in which data, information, and knowledge are new materials. Whatever the purpose of the engineering effort, the engineer is an information processor who is constantly faced with the problem of effectively acquiring, using, producing, and transferring data, Information, and knowledge.

While acknowledging that other models exist (see Wilkins^[3] for a discussion of other models), we have chosen to view the information-seeking behavior of engineers within a conceptual framework of the engineer as an

information processor. This article uses the chosen framework to discuss information-seeking behavior of engineers, reviewing selected literature and empirical studies from library and information science, management, communications, and sociology. The article concludes by proposing a research agenda designed to extend our current, limited knowledge of the way engineers process information.

BACKGROUND

Stevens^[4] and Paisley^[5] provide useful discussions of information in terms of history, definitions, and frameworks for analysis. The concept of information-seeking is imbedded in studies of users, use, and uses. These studies constitute “one of the most extensive and amorphous areas of research in library and information sciences over the better part of four decades.”^[6] (See the *Annual Review of Information Science and Technology* for reviews of information needs and use). The majority of the studies, and certainly the early studies, concentrated on the uses of scientific and technical information (STI). In the majority of these STI usage studies however, scientists, not engineers, were the subjects of investigation.

The literature regarding the information-seeking behavior of engineers is fragmented and superficial. The results of these studies have not accumulated to form a significant body of knowledge. The difficulty in applying the results of these studies has been attributed to the lack of a unifying theory, standardized methodology, and

common definitions. With specific reference to engineers, the difficulty may be attributed to the failure of researchers to take into account the essential difference between science and technology and, similarly, between engineers and scientists.^[7] This fundamental difference is emphasized by Vincenti^[8] in his analysis of the role of knowledge in technological developments.

Engineering is a process dominated by engineers and technology as opposed to scientists and science. As Joenk points out, this fact “leads to different philosophies, habits, and behaviors not only about contributing to the technical literature but also to using the technical literature and other sources of information.”^[9] Recent interest in the information-seeking behavior of engineers corresponds to rising interest and concerns regarding industrial competitiveness and technological innovation. Consequently, an understanding of the information-seeking behavior of engineers is essential to predicting information use and to planning, developing, and implementing engineering information systems. Such an understanding is also critical to enhancing economic competitiveness, improving productivity, and maximizing the process of technological innovation.

THE WORLD OF ENGINEERING

According to the U.S. Bureau of Labor Statistics, engineers held almost 1,411,000 jobs in 1988. About half of these jobs were located in manufacturing industries: about 511,000 were located in nonmanufacturing industries; and about 185,000 were employed by federal, state, and local governments. About one-third of these jobs (439,000) were held by electrical engineers followed, in decreasing order of frequency, by mechanical (225,000), civil (186,000), and industrial (132,000) engineers. A bachelor's degree in engineering from an accredited engineering program is generally acceptable for beginning engineering jobs. Most engineering degrees are granted in branches such as electrical, chemical, or nuclear engineering. Within these branches, most engineers specialize; more than 25 major specialties are recognized by professional societies. *The Occupational Outlook Handbook*^[10] lists and discusses the ten branches of engineering: aerospace; chemical; civil; electrical and electronics; industrial; mechanical; metallurgical, ceramic, and materials; mining; nuclear; and petroleum.

Formal registration is a requirement in the United States for engineers whose work may affect life, health, or property, or who offer their services to the public. Registration generally requires, in addition to a degree from an engineering program accredited by the Accreditation Board for Engineering and Technology (ABET), four years of relevant work experience and satisfactory performance on a state examination.

The engineering profession cannot be described fully without reference to the nature of engineering work, knowledge, and communication. These three areas are also important in establishing the conceptual framework of the engineer as an information processor.

ENGINEERING WORK

What is engineering work like? What tasks and activities are performed by engineers on a day-to-day basis? Florman,^[11] an engineer who has written extensively on the nature of the professional, proclaims that

the essence of engineering lies in its need and willingness to embrace opposites. Empiricism and theory, craftsmanship and science, workshop and laboratory, apprenticeship and formal schooling, private initiative, and government venture, commerce and independent professionalism, military necessity and civic benefit—all of these and more have their place.^[11]

In trying to sort out the diversity of engineering, Adams notes that it may be categorized according to, among other things, particular industries, fields, disciplines, job functions, and end products. He concludes that engineering is interlocked with science, mathematics, and business in a complex environment that “requires a multidimensional map for understanding.”^[12]

The characteristic activity of engineers is making things. Expressed more formally, engineering is usually defined as the application of scientific knowledge to the creation or improvement of technology for human use.^[13] The term “technology” as used in the context of describing engineering work encompasses products, systems, structures, and processes. Engineering work is often described as a process that originates with the first idea for a new or improved technology that is put into use. The National Research Council, for example, describes what it calls “the product realization process” as extending “over all phases of product development from initial planning to customer follow-up.”^[14] Phases in this process include: definition of customer needs and product performance requirements, planning for product evolution, planning for design and manufacturing, product design, manufacturing process design, and production.

Engineering work can also be described in terms of the kinds of tasks and activities that engineers perform on a day-to-day basis. Because of the multidimensional nature of engineering work and the extensiveness of the product development process, engineers perform a wide variety of tasks. Engineering work involves cognitive activities and physical tasks that include the technical and the nontechnical, the routine and the creative, the rational and the serendipitous. According to Ritti,^[15] engineering work consists of scientific experimentation, mathematical analysis, design and drafting, building and testing of

prototypes, technical writing, marketing, and project management. Murotake calls attention to the nontechnical elements of engineering work: “the process of engineering work is not only a technical one, but a social one in which management, communication, and motivation influence the efficiency, quality, and innovativeness of the project team’s work.”^[16] If the characteristic physical activity of engineering is making things, the characteristic cognitive activity is problem-solving. Laudan notes that “change and progress in technology is achieved by the selection and solution of technological problems, followed by choice between rival solutions.”^[17]

The great variety in the nature of the tasks and activities that comprise engineering work is often reflected in the individual engineer’s work, as well. Kemper notes that the typical engineer is likely to define problems, come up with new ideas, produce designs, solve problems, manage the work of others, produce reports, perform calculations, and conduct experiments.^[13] Hollister also describes the work of an engineer as multifaceted: “He begins with an idea, a mental conception. He conducts studies, and when necessary, research into the feasibility of this idea. He directs the building and operation of what he has planned.”^[18] Mailloux highlights the centrality of knowledge production and transfer to engineering work. She reports that about

20% of an engineer’s time is spent in the intellectual activities of engineering—conceiving, sketching, calculating, and evaluating—with the remaining 80% spent on activities associated with creating, accessing, reviewing, manipulating, or transferring information.^[19]

Although engineers perform many tasks independently, most products result from team effort, requiring engineers to share their knowledge and the result of their work with others.^[20] For complex products, teamwork is required at each stage of the engineering process. The literature on concurrent engineering indicates that teamwork is a natural requirement of the need to integrate the various stages of the engineering process. (see, e.g., Stoll^[21]). Bringing a high-quality product to market in an efficient manner often requires, for example, that design engineers communicate with managers, manufacturing and marketing staff within their firm as well as with people outside their organizations, such as clients, funders, and suppliers.

Engineering work takes place in a variety of environments, depending not only on the nature of the product being developed and the stage of product development, but also on the type of employing organization. Organizations employing engineers include universities, research centers, government laboratories and agencies, and private sector manufacturers and consulting firms. The basic goal of engineering is to produce usable products in the shortest possible time at the lowest possible cost. This goal drives the work and communication activities of virtually all

engineers, but it is manifested to a different degree in different employment settings.

ENGINEERING KNOWLEDGE

What kinds of knowledge do engineers need to perform the tasks and activities described above? How is knowledge acquired? Engineering work and knowledge are so closely intertwined, that it is difficult to discuss one without the other. As noted by Vincenti, “. . . engineering knowledge cannot—and should not—be separated from engineering practice. The nature of engineering knowledge, the process of its generation, and the engineering activity it serves form an inseparable whole.”^[8] Engineering practice, in other words, involves both knowing and doing. Even the popular literature suggests the wide variety of knowledge needed by engineers, due to the diversity of their work:

[The engineer’s] task is not alone that of contrivance with material things, for which he must possess an extensive working knowledge of scientific principles and facts. He must also thoroughly understand the functions to be performed by the projected work when it is completed, the methods of its manufacture and construction, and the economics that govern its use. He must have an understanding of the crafts that are to be used and of the organization of the work. It is his responsibility to coordinate and guide the contributions of labor, machines, money, and ideas, and to exert the control necessary to attain his objectives within the prescribed limits of time, cost, and safety.^[18]

Scholarly literature on the nature and generation of engineering knowledge reinforces such popular accounts. Donovan asserts that the range of scientific and technical knowledge used by engineers includes “not only the more formal types of experimental and theoretical knowledge but also all forms of practical skill and tacit understanding as well . . .”^[22]

Schön rejects the model of technical rationality which is typically applied to scientific and technical professions and paints instead a different picture of engineering knowledge. He argues that the situations encountered by practicing professionals are increasingly characterized by “complexity, uncertainty, instability, uniqueness, and value conflicts”;^[23] such situations require intuitive, artistic, and ethical responses in addition to purely technical and rational ones. Schön labels this model of professional work “tacit knowing-in-action”^[23] and describes the development of a new process to produce a desired gun-metal color to illustrate his argument. He represents the activities of the mechanical engineers involved in this project as “a reflective conversation with the materials of the situation . . . [that] wove its way through stages of diagnosis, experiment, pilot process, and production design.”^[23] Throughout this process, experiments are used

to explore puzzling phenomena, test the applicability of potentially useful theories, or achieve particular technological effects. These experiments, however, often produce unanticipated phenomena and outcomes, which then trigger new hypotheses, questions, and goals.^[23] Schön's analysis of this and other examples suggests that the knowledge required to reach a technological solution is derived from the integration of intuition, past experience, creativity (often in the form of analogy development), theory, experimentation, and reflective thinking that occur in a particular problematic situation. He also argues that engineering solutions incorporate social and ethical considerations.

As these accounts suggest, the notion of tacit knowledge permeates discussions of engineering work. Tacit knowledge is knowledge that cannot be articulated. Polanyi describes tacit knowledge—part experience, part intuition, part tactile sensation—as combining “knowing what” and “knowing how” and declares that it is expressed in such actions as expert diagnoses, the performance of skills, and the use of tools.^[24] Another important type of engineering knowledge, visual information, is also expressed in a nonverbal manner. The importance of visual information in technological work is the subject of a paper by Ferguson and is also discussed by Breton.^[25] Layton^[26] describes this phenomenon, too: “technologists display a plastic, geometrical, and to some extent nonverbal mode of thought that has more in common with that of artists than that of philosophers.”^[26] The importance of these two nonverbal modes of thought is rooted in the essence of engineering as the production of physically encoded knowledge. Engineers must know how to make things, and the results of this knowledge are, first and foremost, encoded in the technologies produced. Engineers rely heavily on nontextual information, such as interpersonal communication, drawings, and the examination of physical objects, to acquire the knowledge they need to perform their work.

Holmfeld found three common mechanisms for generating needed knowledge in engineering work. Engineers rely on the “cut and try” method to refine and fine tune.^[20] They also frequently search their memories for familiar concepts and designs in order to increase their confidence in some new variation.^[20] Finally, they make use of that scientific knowledge which they deem to be relevant and readily applicable. This knowledge is often in the form of a simple fact, such as the optimum hole size or speed rotation, resulting from scientific work.^[20] A number of other writers also note that engineers adopt, at times, the methods used by scientists to generate knowledge. Florman describes engineering work as encompassing both theory and empiricism.^[11] Ziman writes that

technological development itself has become ‘scientific’: it is no longer satisfactory, in the design of a new

automobile, say, to rely on rule of thumb, cut and fit, or simple trial and error. Data are collected, phenomena are observed, hypotheses are proposed, and theories are tested in the true spirit of the hypothetico-deductive method.^[27]

Constant presents a detailed history of the origin of the modern jet engine, a revolutionary technological advance. He presents a “variation-retention” model of technological change that is based on the process of random variation and selective retention that occurs in biological organisms. Technological conjecture, which can occur as a result of knowledge gained from either scientific theory or engineering practice, yields potential variations to existing technologies. These variations are subsequently tested, and successful variations are retained.^[28] In the case of the turbojet revolution, technological conjecture was based on engineers’ knowledge of scientific theories. The design, development, and testing of systems that resulted in the retention of the most successful variation involved, on the other hand, the technical and craft knowledge needed to carry out those tasks.

Vincenti traces five “normal” (as opposed to revolutionary) developments in the history of aerospace engineering to detail what he calls “the anatomy of engineering design knowledge.”^[8] His examples reveal that technological developments require a range of scientific, technical and practical knowledge as well as information about social, economic, military, and environmental issues. Vincenti conducts three important analyses of engineering knowledge. The first involves his own elaboration of the variation-selection model of the growth of technological knowledge. Vincenti concludes, after examining numerous examples from history, that the mechanisms for producing variations in engineering design include three types of cognitive activities:^[8] searching past experience to find knowledge that has proved useful, including the identification of variations that have not worked; incorporating novel features thought to have some chance of working; and “winnowing” the conceived variations to choose those most likely to work. Vincenti notes that these activities occur in an interactive and disorderly fashion. Selection occurs through physical trials such as everyday use, experiments, simulations (e.g., the use of wind tunnels), or analytical tests such as the production of sketches of proposed designs, calculations, and other means of imagining the outcome of selecting a proposed variation.^[8]

Vincenti also proposes a schema for engineering knowledge that categorizes knowledge as either descriptive (factual knowledge), prescriptive (knowledge of the desired end), or tacit (knowledge that cannot be expressed in words or pictures but is embodied in judgment and skills). Descriptive and prescriptive knowledge are explicit; tacit knowledge is implicit. Both tacit and prescriptive knowledge are procedural and reflect a “knowing how.”^[8] Finally, Vincenti enumerates and defines specific

engineering knowledge categories: fundamental design concepts, criteria and specifications, theoretical tools (i.e., mathematical methods and theories and intellectual concepts), quantitative data, practical considerations, and design instrumentalities (i.e., procedural knowledge and judgmental skills).^[8] He then presents a matrix that details how each type of knowledge is acquired. The possible sources of engineering knowledge that he describes include transfer from science or generation by engineers during invention, theoretical and experimental engineering research, design practice, production, or direct trial and operation.^[8]

Communications and management studies confirm the findings of historical and sociological research about the range of knowledge, information, and data needed in engineering work. Ancona and Caldwell investigated the tasks and communication of new product development teams in high technology companies. The authors note that such teams

are responsible not only for the specific technical design of a product, but also for coordinating the numerous functional areas and hierarchical levels that have information and resources necessary to make the new product a success.^[29]

Ancona and Caldwell found that new product teams progress through three phases of activity: creation, development, and diffusion. The communication- and information-intensive tasks that accompany these phases include:^[29]

- Getting to know and trust team members
- Determining the availability of resources
- Understanding what other functional groups think the product can should be
- Investigating technologies for building the product
- Exploring potential markets
- Solving technical problems
- Coordinating the teams' work internally and externally
- Keeping external groups informed
- Building relationships with external groups that will receive the team's output
- Promoting the product with manufacturing, marketing, and service groups.

Ancona and Caldwell conclude that information systems designed to support these changing activities must be flexible and support the team's need to identify and contact relevant external groups, generate and evaluate ideas, and coordinate work. Barczak and Wilemon also look at the communication patterns of new product development teams and find a similar range of communication purposes: to discuss product features, technical issues, customer needs, manufacturing issues, schedules and timing, financial issues, managerial issues, and resources issues.^[30]

THE ENGINEERING COMMUNITY

Engineering work and communication are rooted in the concept of "community." A community is a group of people who maintain social contact with each other and who exhibit common interests, goals, norms of behavior, and knowledge. As members of a profession, engineers share a common knowledge base and set of espoused values. The profession prescribes its own approach to work behavior. Engineering is also a social activity; most work is accomplished as a result of group effort and requires extensive interpersonal communication.

Studies of scientific communities look at the values, norms, knowledge, methods, reward system, and culture shared by community members and frequently underscore the role of interpersonal communication in defining the community and holding it together. (see e.g., Barber-Kuhn^[31–33]). This type of investigation has not often been performed in relation to engineering communities. Gaston notes that "[the problem of the internal workings of the technological community] is virtually unexplored. . . . In contrast to the sociology of the scientific community, little is known about the sociology of the technological community."^[34] Constant also notes the lack of research on technological communities. He writes that "While extensive research has been done on 'invisible colleges,' research fronts, and the community structure of science, there has been little analogous [sic] sociological or historical investigation of technological practice."^[35] Rothstein, pointing to the diversity inherent in engineering, warns that defining the entire profession of engineering as a single community provides a model that is inadequate to describe engineering behavior. He argues that the huge variety of occupations and disciplines in engineering demonstrates that there is no such thing as a single engineering community. Further, he contends that most discussions of professional communities fail to direct enough attention to the nature of professional knowledge and its influence on behavior. He contends that the heterogeneity, rate of change, and degree of specialization of engineering knowledge also lead to the emergence of specific communities in engineering.^[36]

Some work has begun to explore the extent to which members of engineering communities share similar work tasks, goals, and methods; are governed by shared social and technical norms; and engage in extensive informal information exchange among themselves. Laudan finds justification for this approach in that

cognitive change in technology is the result of the purposeful problem-solving activities of members of relatively small communities of practitioners, just as cognitive change in science is the product of the problem-solving activities of the members of scientific communities.^[17]

Layton also contends that "... the ideas of technologists cannot be understood in isolation; they must be seen in the context of a community of technologists . . ."[27] Donovan notes that "the study of engineering knowledge must not be divorced from the social context of engineering" and suggests that "the interplay of social values and theoretical understanding in the evolution of scientific disciplines certainly has its analogues in engineering, although the values and knowledge involved are often quite different."^[22]

Rosenthal discusses the design-manufacturing team in new product development. He says that such teams represent "a community of interest" with a shared commitment to the group effort. The group shares information and advice, as well as instructions and decisions.^[37] He describes the difficulties in merging these two subcommunities or cultures, because design and manufacturing engineers have developed their own "tacit understandings built up through years of working on particular problems with special points of view."^[37]

The notion of an engineering community has also been addressed in connection with aerospace work. Vincenti describes informal communities of practitioners as the most important source of knowledge generation and means of knowledge transfer in aerospace. He defines a community as those involved in work on a particular aerospace development or problem (e.g., fasteners, airfoils, or propellers). Vincenti attributes several functions to these engineering communities. Competition between members supplies motivation, while cooperation provides mutual support. The exchange of knowledge and experience generates further knowledge, which is disseminated by word of mouth, publication, and teaching and is also incorporated into the tradition of practice. The community also plays a significant role in providing recognition and reward. Vincenti describes the particular roles of important types of aerospace engineering institutions, such as government research organizations, university departments, aircraft manufacturers, military services, airlines, professional societies, government regulatory agencies, and equipment and component suppliers.^[8] He concludes, however, that

formal institutions do a complex multitude of things that promote and channel the generation of engineering knowledge. They do not, however, constitute the locus for that generation in the crucial way that informal communities do. Their role . . . is to supply support and resources for such communities.^[8]

Constant also describes aerospace communities as the central locus of technological cognition. He notes that the aeronautical community is, in fact, composed of a multilevel, overlapping hierarchy of subcommunities and he argues that technological change is better studied at the community as opposed to the individual, firm, national, or industry level. Constant describes the community as the embodiment of traditions of practice.^[28]

[Technological traditions of practice] define an accepted mode of technical operation, the conventional system of accomplishing a specified technical task. Such traditions encompass aspects of relevant scientific theory, engineering design formulae, accepted procedures and methods, specialized instrumentation, and, often, elements of ideological rationale. A tradition of technological practice is proximately tautological with the community which embodies it; each serves to define the other. Traditions of practice are passed on in the preparation of aspirants to community membership. A technological tradition of practice has, at minimum, a knowledge dimension, including both software and hardware, and a sociological dimension, including both social structure and behavioral norms.

Constant discusses further the importance of community norms in engineering. He alleges that, at least in connection with complex systems, there are "fundamental social norms governing the behavior of technological practitioners which are very close in structure, spirit, and effect to the norms governing the behavior of scientists."^[28] Such norms guide the development of techniques and instruments and the reporting of data. Constant also argues for the existence of "counternorms" in engineering that are similar to those attributed to scientists by Mitroff.^[38] Constant explains that

Technological practitioners are required to be objective, emotionally neutral, rational, and honest. Yet technological practitioners often are—and protagonists of technological revolution usually are—passionate, determined, and irrationally recalcitrant in the face of unpleasant counter evidence bearing on their pet ideas.^[28]

These descriptions of the world of engineering indicate that the activities performed by engineers are diverse and multifaceted. Engineering is defined as the creation or improvement of technology; as such, it clearly encompasses both intellectual and physical tasks, i.e., both knowing and doing. Engineering work is fundamentally both a social and a technical activity. It is a social activity in that it often involves teamwork, as individuals are required to coordinate and integrate their work. It is also a social activity in that the production of the final product depends on the ability to maintain successful social relationships (e.g., negotiate with vendors, maintain smooth personal relations among members of a work group).

The nature of engineering work suggests that engineers require access to a variety of tools and information resources. Further, the use of these tools and resources and the way they are integrated into engineering work may be planned in some cases and ad hoc in other situations. The engineering community, although it has received little attention from researchers, clearly plays an important role in the conduct of engineering work and the generation and transfer of engineering knowledge, information, and data. From this depiction of the engineering

profession, we now move to the establishment of a broader conceptual framework for our model of engineers as information processors.

TOWARD A CONCEPTUAL FRAMEWORK FOR INVESTIGATING THE INFORMATION BEHAVIOR OF ENGINEERS

Engineers are not scientists. Arguments that a scientist is a more generic term merely implies that the two are one and the same. They are not. The practice of lumping the two groups [engineers and scientists] together is self-defeating in information behavior studies because confusion over the characteristics of the sample has led to conflicting results and to a greater difficulty in developing normative measures for planning, developing, and implementing information systems and policy in either science or technology.

Further, the terms “engineer” and “scientist” are not synonymous. Although the previous section has made it clear that many engineers—especially in high tech branches such as aerospace—perform a variety of empirical and theoretical tasks, the differences in work environment and personal/professional goals between the engineer and scientist prove to be an important factor in determining their information-seeking behavior. The following sections explore the science/technology and scientist/engineer dichotomy.

THE NATURE OF SCIENCE AND TECHNOLOGY

The relationship between science and technology is often expressed as a continuous process or normal progression from basic research (science) through applied research (technology) to development (utilization). This relationship, which is illustrated in Fig. 1, is based on the widely

Fig. 1 The progression from science through technology to development as a continuous process.

held assumption that technology grows out of or is dependent upon science for its development. This “assumed” relationship is the foundation upon which U.S. science policy is based and may help to explain the use of the conventional phrase “scientists and engineers.”

However, the belief that technological change is somehow based on scientific advance has been challenged in recent years. Technological change has been increasingly seen as the adaption of existing technological concepts in response to demand.^[41] Moreover, several years of study that attempted to trace the flow of information from science to technology have produced little empirical evidence to support the relationship.^[40–41] Price, for example, claims,^[42]

The naive picture of technology as applied science simply will not fit the facts. Inventions do not hang like fruits on a scientific tree. In those parts of the history of technology where one feels some confidence, it is quite apparent that most technological advances are derived immediately from those that precede them.

The single-tree concept, shown in Fig. 2, is often used to illustrate the relationship between science and technology as a continuous process. Shapley and Roy argue that such a metaphor is historically inaccurate. In their case for a reorientation of American science policy, they argue that the two-tree concept, which is shown in Fig. 3, is a more accurate metaphor and is much more useful in developing science policy.^[43]

Fig. 2 Science and technology as a single tree.

Fig. 3 Technology and science as separate trees.

Shapley and Roy contend that a normal progression from science to technology does not exist, nor is there direct communication between science and technology.^[43] Allen's 1977 study of transfer of technology and the dissemination of technological information in R&D organizations found little evidence to support the relationship between science and technology as a continuous relationship. Allen concludes that the relationship between science and technology, which is depicted in Fig. 4, is best described as a series of interactions that are based on need rather than on a normal progression.^[44]

According to Allen,^[44] (a) the results of science do progress to technology in the sense that some sciences such as physics are more closely connected to technologies such as electronics, but (b) overall a wide variation exists between science and technology. The need for a (c) device, technique, or scientific understanding influences technology. Technology, in turn, (d) responds to a need and, in doing so, may generate the need for an understanding of certain physical phenomena.^[44] A direct communication system between science and technology does not exist to the extent that communication between science and technology is restricted almost completely to that which takes place through the process of education.

Fig. 4 The progression from science through technology to development as a series of interactions.

Price concludes that science and technology progress independently of one another. Technology builds upon its own prior developments and advances in a manner independent of any link with the current scientific frontier and often without any necessity for an understanding of the basic science underlying it.^[42]

In summarizing the differences between science and technology, Price makes the following 12 points. (1) Science has a cumulating, close-knit structure; that is, new knowledge seems to flow from highly related and rather recent pieces of old knowledge, as displayed in the literature. (2) This property is what distinguishes science from technology and from humanistic scholarship. (3) This property accounts for many known social phenomena in science and also for its surefootedness and high rate of exponential growth. (4) Technology shares with science the same high growth rate, but it shows quite complementary social phenomena, particularly in its attitude to the literature. (5) Technology therefore may have a similar, cumulating, close-knit structure to that of science, but the structure is of the state of the art rather than of the literature. (6) Science and technology each therefore have their own separate cumulating structures. (7) A direct flow from the research front of science to that of technology, or vice versa, occurs only in special and traumatic cases since the structures are separate. (8) It is probable that research-front technology is strongly related only to that part of scientific knowledge that has been passed down as part of ambient learning and education, not to research-front science. (9) Research-front science is similarly related only to the ambient technological knowledge of the previous generation of students, not to the research front of the technological state of the art and its innovation. (10) This reciprocal relation between science and technology, involving the research front of one and the accrued archive of the other, is nevertheless sufficient to keep the two in phase in their separate growths within each otherwise independent cumulation. (11) It is naive to regard technology as applied science or clinical practice as applied medical science. (12) Because of this, one should be aware of any claims that particular scientific research is needed for particular technological breakthroughs, and vice versa. Both cumulations can only be supported for their own separate ends.^[42]

Allen states that the independent nature of science and technology (S&T) and the different functions performed by engineers and scientists directly influence the flow of information in science and technology.^[44] Science and technology are ardent consumers of information. Engineers and scientists both require large quantities of information to perform their work. At this level, there is a strong similarity between the information input needs of engineers and scientists. However, the difference between engineers and scientists in terms of information processing becomes apparent upon examination of their outputs.

Fig. 5 Information processing in science and technology.

Information processing in S&T is depicted in Fig. 5 in the form of an input-output model.^[44] Scientists use information to produce information. From a system standpoint, the input and output, which are both verbal, are compatible. The output from one stage is in a form required for the next stage. Engineers use information to produce some physical change in the world. Engineers consume information, transform it, and produce a product that is information bearing; however, the information is no longer in verbal form. Whereas scientists consume and produce information in the form of human language, engineers transform information from a verbal (or often visual or tacit) format to a physically encoded form. Verbal information is produced only as a byproduct to document the hardware and other physical products produced.

According to Allen, there is an inherent compatibility between the inputs and outputs of the information-processing system of science. He further states that since both are in a verbal format, the output of one stage is in the format required for the next stage.^[44] The problem of supplying information to the scientist becomes a matter of collecting and organizing these outputs and making them accessible. Since science operates for the most part on the premise of free and open access to information, the problem of collecting outputs is made easier.

In technology, however, there is an inherent incompatibility between inputs and outputs. Since outputs are usually in a form different from inputs, they usually cannot serve as inputs for the next stage. Further, the outputs are usually in two parts, one physically encoded and the other verbally encoded. The verbally encoded part usually cannot serve as input for the next stage because it is a byproduct of the process and is itself incomplete. Those unacquainted with the development of the hardware or physical product therefore require some human intervention to supplement and interpret the information contained

in the documentation. Since technology operates to a large extent on the premise of restricted access to information, the problem of collecting the documentation and obtaining the necessary human intervention becomes difficult.

DISTINGUISHING ENGINEERS FROM SCIENTISTS

Engineers and scientists exhibit important differences other than the evident differences in education (degree), technical discipline, and type of work/activity. They share such common psychological needs as survival, security, self-esteem, self-expression, belonging, opportunity for growth, and self-determination. The strength of these needs varies from person to person and fluctuates over time. In a collective sense, engineers and scientists share the following attitudes that are conducive to high productivity:^[45]

- effective communication
- optimum salary band benefits
- freedom and authority
- optimum utilization

There are also differences that tend to create sharp distinctions between the two groups. At the risk of inviting a charge of “overgeneralization,” Peake offers the list of differences shown in Table 1.

Danielson investigated engineers and scientists in an attempt to identify those characteristics that affect their motivation and utilization. He concluded that there are recognizable differences between the two groups. He concluded that engineers and scientists are fundamentally different in terms of how they approach their job, the type and amount of supervision required, the type of recognition desired, the personality traits exhibited, and the differences in their goals.^[46]

In their study of the values and career orientation of engineering and science undergraduate students, Krulee and Nadler found that engineering and science students have certain aspirations in common: to better themselves and to achieve a higher socioeconomic status than that of their parents. They report that science students place a higher value on independence and on learning for its own sake, while engineering students are more concerned with success and professional preparation. Many engineering students expect their families to be more important than their careers as a source of satisfaction, but the reverse pattern is more typical for science students.^[47]

Krulee and Nadler also determined that engineering students are less concerned than science students with what one does in a given position and more concerned with the certainty of the rewards to be obtained. They report that, overall, engineering students place less emphasis on independence, career satisfaction, and the inherent interest their specialty holds for them and place more

Table 1 Peake's list of differences between engineers and scientists

Most engineers	Most scientists
Do development, design or applications work	Do research, basic or applied
Apply scientific knowledge	Seek new knowledge
Have engineering degree	Have science degree
Recognize managerial authority	Respect "colleague" authority
Want assignments to good, challenging projects	Want freedom to select their own projects
Like a company with a good record of engineering accomplishment	Like a company with a reputation for scientific advancement
Are hardware oriented	Are software oriented
Dislike preparing talks and publications	Insist on freedom to publish their work
are company oriented (i.e., committed to a variety of work areas, tasks, positions)	Are career oriented (i.e., committed to limited kinds of work areas, tasks, positions)
Dislike ambiguous, uncertain situations	Can work effectively with ambiguity, uncertainty
Are interested in processes, results, realizations	Are interested in concepts, meanings, abstractions
Believe in equalitarian group practices	Believe in authoritarian group practices
Expect to be faced with work schedules, deadlines, constrained resources	Abhor schedules, believe schedules should be self-determined, desire autonomy

value on success, family life, and avoiding a low-level job. Engineering students appear to be prepared to sacrifice some of their independence and opportunities for innovation in order to realize their primary objectives. Engineering students are more willing to accept positions that will involve them in complex organizational responsibilities and they assume that success in such positions will depend upon practical knowledge, administrative ability, and human relations skills.^[47]

In his study of engineers in industry, Ritti found marked contrast between the work goals of engineers and scientists. Ritti draws the following three conclusions from his study: (1) the goals of engineers in industry are very much in line with meeting schedules, developing products that will be successful in the marketplace, and helping the company expand its activities; (2) while both engineers and scientists desire career development or advancement, for the engineer advancement is tied to activities within the organization, while advancement for the scientist is dependent upon the reputation established outside of the organization; and (3) while publication of results and professional autonomy are clearly valued goals of the Ph.D. scientist, they are clearly the least valued goals of the baccalaureate engineer.^[15]

Allen states that the type of person who is attracted to a career in engineering is fundamentally different from the type of person who pursues a career as a scientist. He writes that

perhaps the single most important difference between the two is the level of education. Engineers are generally educated to the baccalaureate level; some have a master's degree while some have no college degree. The research scientist is usually assumed to have a doctorate. The long, complex process of academic socialization involved in obtaining the Ph.D. is bound to result in persons who differ considerably in their lifeworlds.

According to Allen, these differences in values and attitudes toward work will almost certainly be reflected in the behavior of the individual, especially in their use and production of information.^[5]

According to Blade, engineers and scientists differ in training, values, and methods of thought. Further, Blade states that the following differences exist in their individual creative processes and in their creative products: (1) scientists are concerned with discovering and explaining nature; engineers use and exploit nature; (2) scientists are searching for theories and principles; engineers seek to develop and make things; (3) scientists are seeking a result for its own ends; engineers are engaged in solving a problem for the practical operating results; and (4) scientists create new unities of thought; engineers invent things and solve problems. Blade states that "this is a different order of creativity."^[48]

INFLUENCE ON INFORMATION BEHAVIOR

Communications in engineering and science are fundamentally different. Communication patterns differ because of the fundamental differences between engineering and sciences and because of the social systems associated with the two disciplines. Holmfeld offers the following examples of how the social systems affect the communication behavior of engineers and scientists.^[20]

Engineer

- Contribution is [technical] knowledge used to produce end items or products
- New and original knowledge is not a requirement
- Reward is monetary or materialistic and serves as an inducement to continue to make further contributions to technical knowledge

- Seeking rewards that are not part of the social system of technology is quite proper and also encouraged
- The value of technical knowledge lies in its value as a commodity of indirect exchange
- Exchange networks found in the social system of technology are based on end-item products, not knowledge
- Strong norms against free exchange or open access to knowledge with others outside of the organization exist in the social system of technology
- Restriction, security classification, and proprietary claims to knowledge characterize the social system of technology

Scientist

- Contribution is new and original knowledge
- Reward is social approval in the form of professional [collegial] recognition
- Recognition is established through publication and claim of discovery
- A well-developed communication system based on unrestricted access is imperative to recognition and claim of discovery
- Since recognition and priority of discovery are critical, strong norms against any restriction to free and open communication exist in the social system of science
- Seeking rewards that are not part of the social system of science in return for scientific contribution is not considered proper within the social system of science
- Exchange networks commonly referred to as “invisible colleges” exist in the social system of science; in these networks the commodities are knowledge and recognition.^[49–50]

Taylor,^[51] who quotes Brinberg,^[52] offers the following characteristics for engineers and scientists:

Unlike scientists, the goal of the engineer is to produce or design a product, process, or system; not to publish and make original contributions to the literature. Engineers, unlike scientists, work within time constraints; they are not interested in theory, source data, and guides to the literature nearly so much as they are in reliable answers to specific questions [39–40].

Anthony et al. suggest that engineers may have psychological traits that predispose them to solve problems alone or with the help of colleagues rather than finding answers in the literature. They further state that

engineers like to solve their own problems. They draw on past experiences, use the trial and error method, and ask colleagues known to be efficient and reliable instead of searching or having someone search the literature for them. They are highly independent and self-reliant without being positively anti-social.^[53]

According to Allen,

engineers read less than scientists, they use literature and libraries less, and seldom use information services which are directly oriented to them. They are more likely to use specific forms of literature such as handbooks, standards, specifications, and technical reports.^[44]

What an engineer usually wants, according to Cairns and Compton, is “a specific answer, in terms and format that are intelligible to him—not a collection of documents that he must sift, evaluate, and translate before he can apply them.”^[54] Young and Harriott report that

the engineer’s search for information seems to be based more on a need for specific problem solving than around a search for general opportunity. When engineers use the library, it is more in a personal-search mode, generally not involving the professional (but nontechnical) librarian.^[55]

Young and Harriot conclude by saying that

when engineers need technical information, they usually use the most accessible sources rather than searching for the highest quality sources. These accessible sources are respected colleagues, vendors, a familiar but possibly outdated text, and internal company [technical] reports. He [the engineer] prefers informal information networks to the more formal search of publicly available and cataloged information.^[55]

MAJOR EMPIRICAL STUDIES OF ENGINEERING INFORMATION BEHAVIOR

Studies concerned with the information-seeking behavior of engineers were reviewed by Pinelli^[56] to further develop the conceptual framework. Table 2 lists those major research studies deemed significant to this topic and which are discussed in this section.

HERNER^[57]

Herner’s work is one of the first “user” studies specifically concerned with “differences” in information-seeking behavior. He reports significant differences in terms of researchers performing “basic and applied” research, researchers performing “academic and industry” type duties, and their information-seeking behavior. Herner states that researchers performing “basic or academic” duties make greater use of formal information channels or sources, depend mainly on the library for their published material, and maintain a significant number of contacts outside of the organization.

Table 2 Overview of Engineering Information Behavior Studies.

Principal Year	Investigator	Research Method	Population	Sample Frame	Sample Design	Sample Size	Percentage Response Rate (number responding)	Description
1954	Herner ^[57]	Structured interview	All scientific and technical personnel at Johns Hopkins	Unknown	Unknown	600	100	Survey to determine the information- gathering methods of scientific and technical personnel at Johns Hopkins
1970	Rosenbloom and Wolek ^[58]	Self-administered questionnaire	Members of 5 industrial R&D organizations Members of 4 IEEE interest groups	2430 Unknown	Census Probability	2430 Unknown	71 (1735) Unknown (1034)	Survey to determine how engineers and scientists in industrial research and development organizations acquire STI
1977	Allen ^[44]	Record analysis Self-administered questionnaire	Unknown	Unknown	Unknown	Unknown	Unknown (1153)	Survey to determine technology transfer and the dissemination of technological information in research and development organizations
1980	Kremer ^[57]	Self-administered questionnaire	All design engineers at one engineering design firm	73	Census	73	82 (60)	Survey to identify and evaluate the information channels used by engineers in a design company
1981	Shuchman ^[60]	Structured interview Self- administered questionnaire	Engineers in 89 R&D and non-R&D organizations	14797	Probability	3371	39 (1315)	Survey to determine information used and production in engineering
1983	Kaufman ^[61]	Self-administered questionnaire	Engineers in six technology-based organizations	147	Census	147	100 (147)	Survey to determine the use of technical information in technical problem solving

Researchers performing “applied or industry” duties make greater use of informal channels or sources, depend on their personal collections of information and colleagues for information, make significantly less use of the library than do their counterparts, and maintain fewer contacts outside of the organization. Applied or industry researchers make substantial use of handbooks, standards, and technical reports. They also read less and do less of their reading in the library than do their counterparts.

ROSENBLOOM AND WOLEK^[58]

In 1970, Rosenbloom and Wolek published the results of one of the first “large-scale” industry studies that was specifically concerned with the flow of STI within R&D organizations. They report three significant and fundamental differences between engineers and scientists: (1) engineers tend to make substantially greater use of information sources *within* the organization than do scientists; (2) scientists make considerably greater use of the professional (formal) literature than do engineers; and (3) scientists are more likely than engineers to acquire information as a consequence of activities directed toward general competence rather than a specific task.

In terms of interpersonal communication, the engineers in the Rosenbloom and Wolek study recorded a higher incidence of interpersonal communication with people in other parts of their own corporation, whereas scientists recorded a greater incidence of interpersonal communication with individuals employed outside their own corporation. When using the literature, the engineers tended to consult in-house technical reports or trade publications, while the scientists made greater use of the professional (formal) literature.

Rosenbloom and Wolek also report certain similarities between engineers and scientists. The propensity to use alternative types of technical information sources is related to the purposes that will give meaning to the use of that information. Work that has a professional focus draws heavily on sources of information external to the user’s organization. Work that has an operational focus seldom draws on external sources, relying heavily on information that is available within the employing organization. Those engineers and scientists engaged in professional work commonly emphasize the simplicity, precision, and analytical or empirical rigor of the information source. Conversely, those engineers and scientists engaged in operational work typically emphasize the value of communication with others who understand and are experienced in the same real context of work.

ALLEN^[44]

Allen’s study of technology transfer and the dissemination of technological information within the R&D organization is the result of a 10-year investigation. Allen describes the

study, which began as a “user study,” as a systems-level approach to the problem of communication in technology. Many information professionals consider his work to be the seminal research on the flow of technical information within R&D organizations. Allen was among the first to produce evidence supporting different information-seeking behaviors for engineers and scientists. These differences, Allen notes, lead to different philosophies and habits regarding the use of the technical literature and other sources of information by engineers. The most significant of his findings is the relative lack of importance of the technical literature in terms of generating new ideas and in problem definition, the importance of personal contacts and discussions between engineers, the existence of technological “gatekeepers,” and the importance of the technical report. Allen states that “the unpublished report is the single most important informal literature source; it is the principal written vehicle for transferring information in technology.”^[44]

KREMER^[57]

Kremer’s study was undertaken to gain insight on how technical information flows through formal and informal channels among engineers in a design company. The engineers in her study were not involved in R&D. The reason given most frequently to search for information is problem solving; colleagues within the company are contacted first for needed information, followed by colleagues outside of the company. In terms of the technical literature, handbooks are most important, followed by standards and specifications. Libraries are not important sources of information and are used infrequently by company engineers.

Regardless of age and work experience, design engineers demonstrate a decided preference for internal sources of information. They consult personal files for needed information. The perceived accessibility, ease of use, technical quality, and amount of experience a design engineer has had with an information source strongly influence the selection of an information source. Technological gatekeepers exist among design engineers; they are high technical performers and a high percentage are first line supervisors.

SHUCHMAN^[60]

Shuchman’s study is a broad-based investigation of information transfer in engineering. The respondents represent 14 industries and the following major disciplines: civil, electrical, mechanical, industrial, chemical and environmental, and aeronautical. Seven percent, or 93 respondents, were aeronautical engineers. The engineers, regardless of discipline, display a strong preference for informal sources of information. Further, these engineers rarely find all the information they need for solving technical problems in one source; the major difficulty

engineers encounter in finding the information they need to do their job is identifying a specific piece of missing data and then learning who has it.

In terms of information sources and solving technical problems, Shuchman reports that engineers first consult their personal store of technical information, followed in order by informal discussions with colleagues, discussions with supervisors, use of internal technical reports, and contact with a “key” person in the organization who usually knows where the needed information may be located. A small proportion of the engineering profession uses technical libraries and librarians.

In general, Shuchman finds that engineers do not regard information technology as an important adjunct to the process of producing, transferring, and using information. While technological gatekeepers appear to exist across the broad range of engineering disciplines, their function and significance are not uniform; considering the totality of engineering, gatekeepers account for only a small part of the information transfer process.

KAUFMAN^[61]

Kaufman’s study is concerned with the factors relating to the use of technical information by engineers in problem solving. The study reported that, in terms of information sources, engineers consult their personal collections first, followed by colleagues and then by formal literature sources. In terms of the formal literature sources used for technical problem solving, engineers use technical reports, followed in order by text books, and technical handbooks.

Most sources of information, according to Kaufman, are found primarily through an intentional search of written information, followed by personal knowledge and then by asking someone. The criteria used in selecting all information sources, in descending order of frequency, are accessibility, familiarity or experience, technical quality, relevance, comprehensiveness, ease of use, and expense. Engineers use various information sources for specific purposes. They primarily utilized librarians and information specialists to find leads to information sources. Engineers used online computer searches primarily to define the problem and technical literature to learn techniques applicable to dealing with the problem. They rely primarily on personal experience to find solutions to the problem.

Kaufman reports that the criteria used in selecting the most useful information sources, in descending order of frequency, are technical quality or reliability, relevance, accessibility, familiarity or experience, comprehensiveness, ease of use, and expense. In terms of the effectiveness, efficiency, and usefulness of the various information sources, personal experience is rated as the most effective in accomplishing the purpose for which it is used; librarians and information specialists receive the lowest rating for efficiency and effectiveness. Most engineers use

several different types of information sources in problem solving; however, engineers do depend on their personal experience more often than on any single specific information source.

ENGINEERS AS INFORMATION PROCESSORS

To establish a specific conceptual and organizing framework for further research on information use by engineers, engineering can be viewed as an information processing system that must deal with work-related uncertainty through patterns of technical communications. Throughout the process, data, information, and knowledge are being acquired, produced, transferred, and used. The fact that these data, information, and knowledge may be physically or hardware encoded should not detract from the observation that the process of engineering is fundamentally an information processing activity.

The concept of engineering as an information processing entity represents an extension of the arguments developed by Tushman and Nadler.^[62] The concept has its roots in open systems theory developed by Katz and Kahn.^[63] The major work on organizations and work-related uncertainty can be traced to, among others, Galbraith and Duncan,^[64] who have conceptualized organizations as information processing systems.

Uncertainty, defined as the difference between information possessed and information required to complete a task, is central to the concept of engineering as an information processing activity. Rogers^[65] states that coping with uncertainty is the central concept in information behavior. The process of engineering is one of grappling with the unknown. These unknowns or uncertainties may be technical, economic, or merely the manifestations of personal and social variables. When faced with uncertainty, engineers typically seek data, information, and knowledge. In other words, data, information, and knowledge are used by engineers to moderate technical uncertainty. Because engineering always entails coping with a relatively high degree of uncertainty, engineering can certainly be viewed as an informational process. Consequently, information behavior and patterns of technical communication cannot be ignored when studying engineers.

AN ORGANIZING MODEL FOR RESEARCH

The conceptual framework, shown in Fig. 6, represents an extension of Orr’s scheme of the engineer as an information processor. The framework focuses on information-seeking and assumes that, individual differences notwithstanding, an internal, consistent logic governs the information-seeking behavior of engineers.^[66]

A project, task, or problem that precipitates a need for information is central to the conceptual framework for this

Fig. 6 The engineer as an information processor: A structure analysis with data on variables related to information-seeking behavior.

research. This need for information may, in turn, be *internally* or *externally* induced and is referred to by Orr as *inputs* or *outputs*, respectively. Orr,^[66] who cites the work of Voight,^[67] Menzel,^[68] Storer,^[69] and Hagstrom,^[70] states that inputs originate within the mind of the

individual engineer and include data, information, and knowledge needed to keep up with advanced in one's profession, to perform one's professional duties to interact with peers, colleagues, and coworkers, and to obtain stimulation and feedback from them.

Outputs frequently, but not exclusively, result from an external stimulus or impetus. Outputs serve a variety of functions, including responding to a request for information from a supervisor, a coworker, peer, or colleague; reporting progress; providing advice; reacting to inquiries; defending; advocating; and proposing. Inputs and outputs require the use of specific kinds and types of data, information, and knowledge.^[66]

The conceptual framework for this research assumes that, in response to a project, task, or problem, specific kinds or types of data, information, and knowledge are needed. In response to this scenario, engineers are confronted with two basic alternatives: they can create the information through experimentation or observation or they can search the existing information. If they act rationally, the decision to “make or buy” the information will depend upon their subjective perception of the relative likelihood of success in acquiring the desired information by these two alternatives with an acceptable time, and on their perception of the relative cost [money and/or effort] of these alternatives.

If a decision is made to search the existing information, engineers must choose between two information channels. One is the *informal or collegial network*, which is characterized by interpersonal (oral) communications with peers, coworkers, colleagues, gatekeepers, vendors, consultants, “key” personnel, and supervisors and by personal collections of information. The other is the *formal information system*, which includes libraries, technical information centers, librarians and technical information specialists, information products and services, and information storage and retrieval systems. It is assumed that the decision to choose a particular information channel is influenced by institutional and sociometric variables operating within the previously identified systems. Gerstberger and Allen,^[71] Rosenberg,^[72] and Orr^[66] theorize that certain sociometric variables influence information source and product selection.

More recent work highlights the value of exploring contextual and situational variables related to information-seeking and use. Taylor’s theoretical investigation of information use environments emphasizes the importance of understanding the context in which information is sought, conveyed, and applied. Context for professional groups, including engineers, is defined as a combination of the nature of work problems, solutions, and settings associated with particular types of jobs. Taylor assumes, in other words, that members of a profession share tasks, goals, and needs in a way that influences their use of information. Taylor’s analysis recognizes, as Fig. 6 shows, that information-seeking and use is determined by the nature of the particular project, task, problem at hand.^[73]

A shift in emphasis toward the study of cognitive and situational variables surrounding information-seeking and use, and away from users’ personal characteristics and specific systems features, has been advocated by a number

of communications and information science researchers, most notably Dervin and Nilan (see *Annual Review of Information Science and Technology*, 21, 1986). They devote special attention to understanding what there is about a particular situation that encourages an individual to use networks in fulfilling an information need. In Fig. 6, the subjective perception of cost, time, and likelihood of success may often be situationally driven.

The resulting data, information, and knowledge are evaluated subjectively. The engineer as an information processor faces three possible courses of action. *First*, if the acquired-obtained data, information, and knowledge complete the project or task or solve the problem, the process is terminated. *Second*, if the acquired-obtained, data, information, and knowledge are useful but only partially complete the project or task or solve the problem, a decision is made either to continue the process by reevaluating the information source selection or to terminate the process. *Third*, if the acquired-obtained data, information, and knowledge are not applicable to or do not complete the project or task or solve the problem, a decision is made either to continue the process by redefining the project, task, or problem or to terminate the process.

An Empirical Study: The Aerospace Knowledge Diffusion Research Project

We noted earlier that the literature regarding the information-seeking behavior of engineers is fragmented and superficial and that the results have not accumulated to form a significant body of knowledge. The inability to apply these findings is attributable to the lack of a unifying theory, standardized methodology, and common definitions. The simple truth is that little is known about the information-seeking behavior of engineers generally. Further, there is little evidence that addresses differences that may exist among various engineering branches or specialties. We have little knowledge of whether the attributes and information-seeking behaviors associated with engineers in one discipline (e.g., civil) are transferable to engineers in another discipline (e.g., nuclear).

The authors are involved in a research project currently underway that is investigating the production, transfer, and use of federally funded aerospace R&D by aerospace engineers from the perspective of the model presented in Fig. 6. This four-phase project is providing descriptive and analytical data regarding the diffusion of aerospace knowledge at the individual, organizational, national, and international levels. It is examining both the channels used to communicate and the social system of the aerospace knowledge diffusion process. Phase 1 investigates the information-seeking behavior of U.S. aerospace engineers and scientists and places particular emphasis on their use of federally funded aerospace R&D and U.S. government

technical reports. Phase 2 examines the industry-government interface and places special emphasis on the role of information intermediaries in the aerospace knowledge diffusion process. Phase 3 concerns the academic-government interface and places specific emphasis on the information intermediary-faculty-student relationship. Phase 4 explores the information seeking behavior of non-U.S. aerospace engineers and scientists in selected countries. Another portion of the project looks specifically at the use of electronic networks by U.S. aerospace engineers.^[74]

Over the long term, the project findings will provide an empirical basis for understanding the aerospace knowledge diffusion process itself and its implications at the individual, organizational, national, and international levels. The results of the project should provide useful information to R&D managers, information managers, and others concerned with improving access to, the quality of, and the utilization of federally funded aerospace R&D.^[75] Selected descriptive results from this research, as it pertains to the information-seeking behavior of aerospace engineers, are reported in this section.

Patterns of technical communication

The communication of technical information (e.g., producing written materials or oral discussions) is an important aspect of aerospace engineering. Based on a 40-hour week, aerospace engineers spend an average ($\bar{X}$) of 8.7 hours per week writing technical information and 10.3 hours per week communicating technical information orally. Combining these means shows that aerospace engineers spend an average of 19 hours per week communicating in written and oral form. On average, aerospace engineers spend more time per week communicating technical information ($\bar{X} = 19.06$) to others than they do working with technical information received from other ($\bar{X} = 14.64$). As their years of work experience increase and as they advance professionally, so too does the amount of time they spend communicating (i.e., producing and using) technical information.

On average, the majority of aerospace engineers prepare written technical communications alone. Of the approximately 22% who write with a group of engineers, about 40% write with the same group of engineers. The average size ($\bar{X}$) of the group is 5.75 people. Of those who write in or with a group, about 22% indicated that doing so made them more productive than writing alone, and 21% indicated that doing so made them less productive than writing alone. Letters and memos were the technical information products most frequently prepared alone. Drawings/specifications were the technical information product most frequently prepared in a group. Drawings/specifications were the most frequently used technical information product.

Patterns of technical information use and problem solving

Aerospace engineers use a variety of technical information sources when solving technical problems. In general, aerospace engineers are not interested in guides to the literature nearly so much as they are interested in reliable answers to specific questions. They prefer informal sources of information, especially conversations with individuals within their organization. Aerospace engineers may also have psychological traits that predispose them to solve problems alone or with the help of colleagues rather than seeking answers in the literature. When they use libraries, they tend to use them in a self-help mode. When they use them, aerospace engineers tend to turn to librarians and library services for assistance only after they have consulted their personal store of information, talked to co-workers and colleagues, consulted a "key" person, and used a library in a personal search mode. Having failed to that point, aerospace engineers search or have a database searched and/or seek the assistance of a librarian or technical information specialist.

The role of the library

Regardless of their relative position in the problem solving process, libraries and librarians provide an important link in the aerospace engineer's quest for information. Overall, libraries and technical information centers are important ($\bar{X} = 3.8$ with 5 being most important) to aerospace engineers in performing their professional duties. Statistically, academically-affiliated aerospace engineers assign a higher rating of importance to libraries and technical information centers than do their counterparts in government and industry. Academically-affiliated aerospace engineers also tend to use libraries and technical information centers more often than do government- and industry-affiliated aerospace engineers.

Why do aerospace engineers not use libraries and technical information centers? The primary reasons include "no information needs" and "information needs met some other way." There also appears to be a positive correlation between "use" by aerospace engineers and "physical distance." In other words, the closer the aerospace engineer resides to the library, the greater the probable use of the library or technical information center.

Factors affecting use of technical information

The relevant literature overwhelmingly favors accessibility as the single most important (variable) determinant of use. Gerstberger and Allen reported that among R&D engineers, accessibility rather than technical quality influences use.^[71] Allen^[44] stated, "There is apparently some relationship between the perceptions of technical quality

and channel accessibility, but it is the accessibility component that almost exclusively determines frequency of use.”^[44] Rosenberg in a study of research and non-research personnel in industry and government found that both groups exhibited similar information-seeking behavior. Of the eight variable investigated by Rosenberg, both groups indicated that accessibility had the greatest influence on information use.^[72] Orr, on the other hand, disagreed, stating that quality of information was the most important consideration in selecting/using an information product.^[66] Our results indicate that accessibility influences the use of information products by aerospace engineers. However, accessibility does not “exclusively” determine information use. Relevance and technical quality, together with accessibility, are the factors that affect the use of information products by aerospace engineers.

Use of Information Technology

In Shuchman’s investigation^[60] of information transfer in engineering, aeronautical engineers made greater use of information technologies, including computers, than did engineers in other disciplines (see Bishop^[76] and Pinelli^[77] for an overview of recent literature on the use of information technology in aerospace engineering). Study data indicate that aerospace engineers tend to use many forms of information technology and that they are likely to use information if accessible via a computer. Approximately half of all aerospace engineers have access to and use electronic networks. Electronic networks are used by aerospace engineers for various purposes including online database searching; communicating via electronic mail, bulletin boards or conferencing systems; logging into remote computers to run programs; and exchanging data and other files.

The need for theory-based practice

With its contribution to trade, its coupling with national security, and its symbolism of U.S. technological strength, the U.S. aerospace industry holds a unique position in the nation’s industrial structure. However, this industry, in particular the commercial aviation sector, is in the midst of profound change and now faces a significantly more challenging competitive and global environment. To remain a world leader in aerospace, the U.S. must improve and maintain the professional competency of its engineers and scientists, increase the R&D knowledge base, improve productivity, and maximize the integration of recent technological developments into the R&D process. How well these objectives are met, and at what cost, depends on a variety of factors, but largely on the ability of U.S. aerospace engineers and scientists to acquire and process the results of aerospace R&D. Hence, an understanding of the information-seeking behavior of aerospace engineers

would offer valuable insight for maintaining U.S. supremacy in aerospace.

Despite the expenditure of considerable effort, there is no generally accepted or systematically acquired body of research that can accurately describe or explain information-seeking behavior or predict the use of information by engineers in general and aerospace engineers in particular other than at the most elementary levels. A variety of environmental and structural changes, including the growth of computer and information technology, combine to significantly weaken the relevance and reliability of this research. Hence there is the need for a modestly constructed engineering-oriented research agenda.

ENGINEERING INFORMATION-SEEKING BEHAVIOR: DEVELOPING A RESEARCH AGENDA

Considerable research and numerous user studies have been conducted over the past 25 years. The generally held beliefs are that (1) the results of this research and these studies have not accumulated to form a significant body of knowledge that can be used by information professionals and (2) the results that are usable have been virtually ignored by those concerned with the design and provision of information policy, products, services, and systems.

An acquired body of research is vital to the development of theory and the solution of professional problems, to the formation of tools and methods for analyzing organizations, services, environments, and behaviors, to determining the cost and benefits of information products, services, and systems, to establishing and developing theories upon which to base practice, and to contributing paradigms, models, and radically new conceptualizations of information-seeking behavior. The following outline suggests the directions that continued research should take.

1. Previous research regarding the information-seeking behavior of engineers is noncumulative, has been variously criticized, and has largely been dismissed on the basis of research and scholarship.
 - A. Conduct a “critical” review, analysis, and evaluation of previous research, identify and remove spurious research findings, and establish a starting point or foundation for “what is known and accepted as fact” vis-a-vis engineering information-seeking behavior.
 - B. Identify the criticisms and deficiencies of previously used research designs and methodologies and compile a list of “lessons learned” to guard against committing the same or similar mistakes.
 - C. Consider the lessons learned in the context of existing research designs and methodologies and identify those that correct or compensate for previous mistakes.

2. Previous research regarding the information-seeking behavior of the engineer has been limited to a particular system, product, or service in a particular organization or environment. Hence, the results are often confusing, conflicting, and not sufficient to form the basis for the development of theory.
 - A. Develop standard definitions, terms, and terminologies.
 - B. Develop, test, and validate research tools, instruments, and techniques.
 - C. Develop a standard set of variables.
 1. Types of Users
 - a. Engineers
 - b. Scientists
 - c. Intermediaries
 - d. Gatekeepers
 - e. Managers
 2. Types of Organizations
 - a. Academic
 - b. Government
 - c. Industry
 3. Size of Organization
 - a. Small
 - b. Medium
 - c. Large
 4. Types of Environment
 - a. Research
 - b. Development
 - c. Design
 - d. Manufacturing
 - e. Production
 - f. Test and Evaluation
 - g. Marketing and Sales
 - h. Service and Maintenance
 - i. Management
 5. Types of Knowledge
 - a. Tacit knowledge
 - b. Information
 - c. Data
 6. Types of Product/Service
 - a. Print
 - b. Nonprint
 - c. Electronic
 7. Types of Engineering Discipline
 - a. Civil
 - b. Electrical
 - c. Mechanical
 - D. Determine which variable(s) (institutional and situational) best describe and explain the use of information by engineers in a variety of environments.
3. What is known about the information-seeking behavior of engineers seems not to explain information use and nonuse. Hence, there is little knowledge that can

be used for testing existing and developing new paradigms.

- A. Conduct engineering information-seeking behavior research within a conceptual framework that embraces the production, transfer, use, and management of information. One possible outcome could be the identification of barriers that prohibit or restrict the use of information by engineers.
 - B. Seek to understand the diffusion of engineering knowledge as a precursor to describing and explaining the information-seeking behavior of engineers.
 - C. Develop and test hypotheses, the results of which, can lead to the formation of theory that can be used to predict the use of information by engineers.
 - D. Develop a series of experiments, the results of which will lead to the formation of paradigms, models, and radically new conceptualizations of library and information science phenomena.
4. Conventional wisdom states that a “disconnect” exists between researchers and practitioners in the field of library and information science.
 - A. Develop a mechanism that couples the results of basic and applied research with users in the field.
 - B. Develop the means by which researchers and practitioners have greater opportunities for interaction.

Determining what we know and where we are will provide a starting point to formulate the questions that must be asked. The answers to these questions will form the elements of a basic research program and lead to the development of theory-based practice. Applied research can then be used to test and validate these theories. Tests and validation will lead to the identification of spurious findings and eventually to the accumulation of a significant body of knowledge that can be used by information professionals to design aerospace information policy, products, services, and systems.

Encyclopedia of Library and Information Sciences, Fourth Edition

Contents

Volume I

Academic Libraries / Susan Curzon and Jennie Quiñónez-Skinner	1
Accessibility / Lori Bell	14
Accreditation of Library and Information Studies Programs in the United States and Canada / Karen Lynn O'Brien	18
Acquisitions Institute at Timberline Lodge / Scott A. Smith	22
African Librarianship / Natalia T. Bowdoin and Janet Lee	33
Altmetrics / Richard Cave	44
American Association of Law Libraries (AALL) / Kate Hagan	48
American Association of Museums (AAM) / Elizabeth E. Merritt	56
American Association of School Librarians (AASL) / Donald C. Adcock	59
American Library Association (ALA) / Mary W. Ghikas	67
American Medical Informatics Association (AMIA) / Don E. Detmer, Tia Abner and Karen Greenwood	85
American National Standards Institute (ANSI) / Jana Zabinski	87
American Society for Information Science and Technology (ASIST) / Charles H. Davis and Debora Shaw	90
Approval Plans / Robert Nardini	96
Arab Federation for Libraries and Information (AFLI) / Nour Soufi	100
Archival Appraisal and Acquisition / Barbara Reed	105
Archival Arrangement and Description / Joanne Evans, Sue McKemmish and Barbara Reed	115
Archival Documentation / Gavan McCarthy and Joanne Evans	127
Archival Finding Aids / Su Kim Chung and Karla Irwin	133
Archival Management and Administration / Michael J. Kurtz	141
Archival Reference and Access / Mary Jo Pugh	149
Archival Science / Elizabeth Shepherd	166
Archives / Adrian Cunningham	179
Archivists and Collecting / Richard J. Cox	195
Area and Interdisciplinary Studies Literatures and Their Users / Lynn Westbrook	209
ARMA International, Inc. / Carol E. B. Choksy	221
Armenia: Libraries, Archives, and Museums / Sylva Natalie Manoogian	228
Art Galleries / Daniel C. Danzig	241
Art Librarianship / Kathryn M. Wayne	249
Art Museums / David Gordon	259

Volume I (*cont'd.*)

Artificial Intelligence / Jianhua Chen	269
Artificial Neural Networks and Natural Language Processing / Hermann Moisl	279
Arts Literatures and Their Users / Lisl Zach	293
ASLIB / David Bawden and Lyn Robinson	301
Association for Information Science and Technology / Diane H. Sonnenwald, Charles H. Davis and Debora Shaw	311
Association for Information Systems (AIS) / William R. King and Dennis Galletta	318
Association for Library Collections and Technical Services / Charles Wilt	324
Association for Library Service to Children (ALSC) / Virginia A. Walter	333
Association of College and Research Libraries (ACRL) / Mary Ellen Davis and Mary Jane Petrowski	338
Association of Library Trustees, Advocates, Friends and Foundations (ALTAFF) / Sally Gardner Reed	361
Association of Research Libraries (ARL) / Lee Anne George and Julia Blixrud	364
Association of Specialized and Cooperative Library Agencies (ASCLA) / Barbara A. Macikas	376
Australia: Libraries, Archives, and Museums / Alex Byrne	379
Australian Library and Information Association (ALIA) / Sue Hutley, Jane Hardy and Judy Brooker	396
Authentication and Authorization / David Millman	401
Automated Acquisitions / Patricia A. Smith and Allison V. Level	408
Automatic Abstracting and Summarization / Daniel Marcu	418
Automatic Discourse Generation / John A. Bateman	430
Back-of-the-Book Indexing / Nancy C. Mulvany	440
Bibliographic Control [ELIS Classic] / Robert L. Maxwell	447
Bibliographical Society (London) / Julian Roberts	456
Bibliographical Society of America (BSA) / Hope Mayo	463
Bibliography / D. W. Krummel	468
Bibliometric Overview of Information Science / Howard D. White	480
Bibliometric Research: History [ELIS Classic] / Dorothy H. Hertzfel	492
Bibliothèque Nationale de France / Noémie Lesquins	531
Binding [ELIS Classic] / Lawrence S. Thompson	538
Biological Information and Its Users / Kalpana Shankar	554
Blind and Physically Disabled: Library Services / Jane Rosetta Virginia Caulton and Stephen Prine	563
Bliss Bibliographic Classification First Edition [ELIS Classic] / Jack Mills	573
Bliss Bibliographic Classification Second Edition / Vanda Broughton	581
Boolean Algebras [ELIS Classic] / A. R. Bednarek	591
Brazil: Library Science / Mariza Russo	597
Brazil: Library Science—Distance Education / Mariza Russo	603
Brazil: Museums / Regina Dantas and Pamela Howard-Reguindin	611
British Library / Andy Stephens	616
Business Informatics / Markus Helfert	630
Business Information and Its Users / Eileen G. Abels	635
Business Literature: History [ELIS Classic] / Edwin T. Coman, Jr.	643
Canada: Libraries and Archives / Ian E. Wilson and Sean F. Berrigan	654
Canadian Heritage Information Network (CHIN) / Shannon Ross and Paul M. Lima	675
Canadian Library Association (CLA) / Donald I. Butcher	681
Careers and Education in Archives and Records Management / Karen Anderson	685
Careers and Education in Information Systems / Paul Gray and Lorne Olfman	693

Volume I (*cont'd.*)

Careers and Education in Library and Information Science / <i>Jana Varlejs</i>	706
Careers and Education in Records and Information Management / <i>Carol E. B. Choksy</i>	715

Volume II

Cataloging / <i>Daniel N. Joudrey</i>	723
Cataloging Cultural Objects (CCO) / <i>Elizabeth O'Keefe and Maria Oldal</i>	733
Catalogs and Cataloging: History [<i>ELIS Classic</i>] / <i>Eugene R. Hanson and Jay E. Daily</i>	743
Censorship and Content Regulation of the Internet / <i>Peng Hwa Ang</i>	780
Center for Research Libraries / <i>Mary I. Wilke</i>	789
Charleston Conference / <i>Katina Strauch</i>	794
Chartered Institute of Library and Information Professionals (CILIP) / <i>Tim Owen</i>	806
Chemistry Literature and Its Users [<i>ELIS Classic</i>] / <i>Judith N. Currano</i>	814
Chemoinformatics / <i>Peter Willett</i>	830
Children and Information Technology / <i>June Abbas</i>	839
Children's Literature / <i>Judith V. Lechner</i>	852
Children's Services in Libraries / <i>Virginia A. Walter and Melissa Gross</i>	876
China: Libraries, Archives, and Museums / <i>Priscilla C. Yu and TzeHuey Chiou-Peng</i>	886
Circulation Services / <i>Vanessa Irvin and Jeff E. Bullard</i>	916
Citation Analysis / <i>Howard D. White</i>	923
Citation Indexes and the <i>Web of Science</i> / <i>Marie E. McVeigh</i>	940
Citer Motivations [<i>ELIS Classic</i>] / <i>Terrence Brooks</i>	951
Classification Theory / <i>Clare Beghtol</i>	958
Clinical Decision-Support Systems / <i>Kai Zheng</i>	974
College Libraries / <i>Thomas G. Kirk, Jr.</i>	983
Communication and Communication Studies / <i>Brenda Dervin and CarrieLynn D. Reinhard</i>	994

Introduction to the Encyclopedia of Library and Information Sciences, Fourth Edition

How to Use This Encyclopedia

Entries are arranged alphabetically in this encyclopedia (see end papers for alphabetical list). The editors of this edition (ELIS-4) have decided to forego the Topical Table of Contents that was provided in ELIS-3 by editors Marcia Bates and Mary Niles Maack. At the time of publication of ELIS-3, the Topical TOC was crucial for readers to get a sense of how subjects were grouped and an understanding of the field or subfield through the clustering of categorical entries in the print edition. ELIS-4 is envisioned as a primarily online reference work where a Topical TOC does not serve the same purpose. The print edition is served well by the main TOC as well as the detailed index, while entries in the online version are easily discoverable through title, author, keyword, and full text searches.

In sum, relevant entries can be found by

1. Entry title (alphabetical arrangement of entries in the encyclopedia or listing in the end papers)
2. Specific name or keyword, including the index at the end of each volume

If the first name or keyword searched is not found, try several more variations—either different words or a different order of words. Most topics are described in several ways in the literature of a discipline, and the first term or phrase that comes to mind may not be the one used here.

Scope of the Encyclopedia

The title of the third edition, *Encyclopedia of Library and Information Sciences*, ended with the letter “s” because the encyclopedia was broadened to cover a spectrum of related and newly emerging information disciplines, including archival science, document theory, informatics, and records management, among others. The fourth edition continues this trend but with an extensive focus on the aspects of library and information sciences that have been heavily impacted by the adoption and reliance on online information distribution. This focus is reflected in the inclusion of numerous new entries such as digital preservation, altmetrics, web-scale discovery services, demand-driven acquisitions, and global open knowledgebases. Alongside these entries based on entirely new topics, the expanded use of the Internet for information has led to new treatment of traditional LIS topics such as resource description and access (RDA) that reflects the adoption of new standards for cataloging.

ELIS-4 also seeks to build upon the description of professional practice to round out the theoretical perspective that previous editions covered very well. Both current editors are academic research librarians and thus, focused heavily on addressing gaps in the encyclopedia related to academic research information while still relying heavily on the structure established by editors of ELIS-3. For example, ELIS-3 introduced country profiles and ELIS-4 builds upon that with new entries for New Zealand and a third on Brazil, in addition to revisions for Slovakia, Netherlands, Canada, Belarus, Kazakhstan, and Brazil among others. This edition also expands the number of entries for named cultural and information entities that did not appear in previous editions, such as the National Library of Medicine, North American Serials Interest Group (NASIG), the International Association of Scientific, Technical and Medical Publishers (STM), and ASLIB, as well as entities like the HathiTrust that have been established since the last edition was published. A number of new entries describing important information conferences such as the Acquisitions Institute at Timberline, the Charleston Conference, and Electronic Resources in Libraries (ER&L) also help round out the encyclopedia and further the description of the current state of academic research librarianship.

ELIS-4 also continues the tradition of designating important entries of historical or theoretical importance as “ELIS Classics.” These are entries by major figures in the library and information sciences or those that describe core concepts in LIS theory, practice, or education that appeared in earlier editions of the encyclopedia. The current editors preserved the approximately 40 previous “ELIS Classics” and designated 13 previous entries as new “ELIS Classics.”

There are more than 550 entries, of which more than 20 are new, another 93 are revisions to prior entries that have been brought up to date by their authors or by new authors, about 30 are ELIS Classics, and about 400 are reprinted from an earlier edition since they have remained relevant to the present. It is important to note that the editors also had to make some choices related to retiring entries that were no longer relevant—due to the passage of time and the development of the field, the technologies and theories described in those entries were deemed to be out of scope for the new edition and thus not revised or reprinted.

Encyclopedia Authors

As in past editions, the authors writing for the encyclopedia are major researchers, librarians and practitioners, and leaders in the fields and subfields in the disciplines in which they are writing. Noted scholars are well represented, and a number of authors are former leaders in LIS associations, including the American Library Association (ALA), the Association for College and Research Libraries (ACRL), the International Federation of Library Associations and Institutions (IFLA), the American Society for Information Science and Technology (ASIS&T), and the American Association of Library and Information Science Education (ALISE). In addition, there are many contributors who are current or former directors of major institutions. As in past editions, the editors are very proud of the range and diversity of authors who have written these entries for the encyclopedia and we thank them for sharing their expertise with the current and future readers and researchers in the field.

Finally, the editors for ELIS-4 have grappled with the challenges of entry generation that was noted by previous editors in nearly every edition: that not all ideas, topics, and potential entries were able to be completed for publication in this edition. While we made a valiant attempt to include entries identified by ELIS-3 editors but not secured for publication in that edition, we sometimes could not find authors willing to take those topics on. Similarly, we were sometimes unable to secure revisions to entries from new authors when previous authors were unable to perform that task. To the greatest extent possible, we endeavored to replace authors when entries were deemed important enough to appear in ELIS-4 but initial or previous authors had to decline or defaulted. No doubt, the editors of ELIS-5 will also pick up the mantle and attempt to round out the encyclopedia with entries for anything that ELIS-4 missed. As noted by editors Bates and Niles Maack in ELIS-3, this problem of missing topics was also acknowledged by Allen Kent, editor of the first edition of ELIS. Kent stated in 1973, "I have prepared this presentation to make sure the lessons of Diderot-d'Alembert are recalled in terms of encyclopedia-making as an exercise in the art of the possible."

Background and Development of the Encyclopedia

The first edition of ELIS, under the editorship principally of Allen Kent and Harold Lancour, was published between 1968 and 1982. The 33 volumes of the first edition were published in alphabetical sequence during those years. After the "Z" volume appeared in 1982, a number of supplements were published at roughly the rate of two per year, up to and including volume 73, which appeared in 2003. Miriam Drake was appointed editor for the second edition, which appeared in 2003, both online and in paper. The second edition came out at one time in four large-format volumes, with a supplement in 2005 [3]. Kent and Lancour covered a wide range of librarianship, information science, and some computer science topics. Drake, an academic library director, emphasized academic libraries, and the ELIS-2 volumes contained many profiles of major academic libraries and professional library associations.

The third edition, under the editorship of Marcia Bates and Mary Niles Maack, reflected a growing convergence among the several disciplines that concern themselves with information and the cultural record. As information science educators and noted researchers in the field, their focus was on growing the encyclopedia in the theoretical fields of information sciences as well as drawing together the associated information and cultural disciplines such as archival sciences and museum studies within the overall field of LIS.

For this edition, we have focused on developing the encyclopedia to reflect the changing nature of information production and consumption through online and digital forms. We have also endeavored to fill in gaps in the description of important people, places, and theories in the information sciences, and further enhanced the description of important concepts related to the provision of research information and the field's major institutions.

We continue to see the audience for the encyclopedia just as previous editors have: as principally consisting of 1) the educated lay person interested in one or more of its topics, 2) students learning about a topic, and 3) professionals and researchers in the several fields who want to learn about something new, or to be refreshed on a familiar topic.

We honored the previous editors by reengaging their superb Editorial Advisory Board with significant new additions of experts known to the current editors. (See listing in the front matter.) These leaders and experts from as many disciplines as are in the encyclopedia provided excellent guidance and feedback for the editors as they began the process of new topic generation, evaluation of previous entries, and offering to author or review numerous entries throughout the process of publication.

All new and revised entries were reviewed by one or more outside expert reviewer as well as one or more of the editors. Referees provided invaluable feedback to authors, including noting errors or omissions as well as making suggestions on additional aspects of the topic to cover. While we made every reasonable attempt through this process to check the accuracy of every entry and every fact, undoubtedly readers will find some topics explained more thoroughly or accurately than others. Indeed, due to the time frame from the beginning of the generation of the fourth edition and the time of publication, readers will reasonably note that some topics have been quickly superseded due to this passage of time, so the

date of acceptance of the entry will be noted on each entry since several years may have passed since the writing of the entry and the publication of this edition.

Acknowledgments

This edition of the encyclopedia was possible only through the countless hours that the editors, John McDonald and Michael Levine-Clark, spent reviewing the previous encyclopedia entries, outlining the topics that were missing or that were newly emerging in the field, and identifying appropriate expert authors to write those new entries. In addition, the editors devoted extensive time to corresponding with previous authors encouraging them to revise their entries, and finding replacement authors for important entries that needed revisions but whose original authors were unavailable.

Both editors wish to acknowledge the expertise of each other and their knowledge of our field, their extensive network of contacts, and their ability to work closely together to ensure the success of this encyclopedia. Neither of them could have completed this project alone.

They acknowledge and thank the Taylor & Francis Group editors, Claire Miller and Rich O'Hanley, as well as Susan Lee, who passed away at the early stages of the preparation of this edition, and more recently, Alexandra Torres, who supported and kept the editors and authors on track over the course of the years of work on this edition of the encyclopedia.

The editors thank the authors who wrote and revised entries, and the huge number of reviewers who refereed the entries. Without their dedication, expertise, and willingness to share their knowledge with others, there would be no encyclopedia. They also wish to thank the Editorial Advisory Board for their advice, suggestions of topics and authors, their hours spent writing or reviewing for the final edition. They also wish to thank the previous editors, Marcia Bates and Mary Niles Maack, whose organization and structure for ELIS-3 provided an excellent blueprint for ELIS-4.

Epistemology

Paul K. Moser

Department of Philosophy, Loyola University Chicago, Chicago, Illinois, U.S.A.

Abstract

Philosophers and others have long tried to formulate an explanation of the nature, origin, and scope of knowledge. Epistemology is the philosophical project of formulating such an explanation. It has occupied philosophers at least since the time of Plato, and it continues to provide a central field of study in contemporary philosophy. If we claim to have genuine knowledge in any area of inquiry, or information gathering, we should be prepared to offer the kind of explanation of knowledge that is constitutive of epistemology.

INTRODUCTION

Epistemology is the theory of knowledge, the philosophical study of the nature, origin, and scope of knowledge. Classical and contemporary epistemologists have debated (1) what knowledge consists in (e.g., justified true belief); (2) what knowledge is based on (e.g., sensory experience and/or pure reason); and (3) what the extent of our knowledge is (e.g., objective, conceiver-independent facts as well as subjective, conceiver-dependent facts). Debates over such topics have occupied epistemologists since the time of Plato. Contemporary epistemologists have not put an end to such debates by any means, but they have made some distinctive contributions. This entry surveys such topics.

ANALYZING KNOWLEDGE

In analyzing (the concept of) knowledge, epistemologists seek to identify the essential, defining constituents of knowledge. The standard analysis of knowledge stems from Plato's *Theaetetus*, and proposes that knowledge is justified true belief. Despite its distinctive heritage, this analysis faces a serious challenge called "the Gettier Problem." In 1963, Edmund Gettier published a crucial challenge to the view that if you have a justified true belief that *P*, then you know that *P*. One of Gettier's counterexamples to this view is the following. Smith is justified in believing the false proposition that (a) Jones owns a Ford. On the basis of (a), Smith infers, and thus is justified in believing, that (b) either Jones owns a Ford or Brown is in Barcelona. As it happens, Brown is in Barcelona, and so (b) is true. So, although Smith is justified in believing the true proposition (b), Smith does not know (b).

Gettier-style counterexamples illustrate the reality of cases where a person has justified true belief that *P* but lacks knowledge that *P*. The Gettier problem is the problem of

finding a modification of, or an alternative to, the standard analysis of knowledge that sidesteps problems from Gettier-style counterexamples. Many epistemologists take the main lesson of Gettier-style counterexamples to be that propositional knowledge requires a fourth condition beyond the justification, truth, and belief conditions. No specific fourth condition has attracted a consensus, but some approaches to a fourth condition have become prominent. A proposed "defeasibility condition," for example, requires that the justification appropriate to knowledge be "undefeated" in that some appropriate subjunctive conditional concerning defeaters of justification be true of that justification. One simple defeasibility fourth condition requires of Smith's knowing that *P* that there be no true proposition, *Q*, such that if *Q* became justified for Smith, *P* would no longer be justified for Smith. So, if Smith knows, on the basis of visual perception, that Jeanne removed books from the library, then Smith's coming to believe the true proposition that Jeanne's identical twin removed books from the library would not undermine the justification for Smith's belief concerning Jeanne herself. A different approach avoids subjunctive conditionals of that sort, and implies that propositional knowledge requires justified true belief that is sustained by the collective totality of actual truths. This approach requires a detailed account of when justification is undermined and restored. After four decades of vigorous research, however, contemporary epistemologists have still not come up with a widely accepted solution to the Gettier problem. The Gettier problem is, nonetheless, epistemologically important, because our having a precise understanding of propositional knowledge requires our having a Gettier-proof analysis of such knowledge.

MODERN EMPIRICISM

Contemporary Anglo-American epistemology began with the departure of Bertrand Russell (1872–1970) and G. E.

Moore (1873–1958) from Kantian and Hegelian idealism. They opposed idealism not only with the ontological claim that there are mind-independent facts, but also with the epistemological claim that they *know* that there are such facts. The ground for the latter epistemological claim, according to Russell, is “common sense, uninfluenced by philosophy or theology.”^[29]

What exactly is common sense? Surprisingly, Russell and Moore do not say in any detail. Russell speaks of common sense *uninfluenced by philosophy or theology*. Why, however, should we regard such common sense as a philosophically adequate ground for challenging idealism and supporting its opposite, realism? In particular, why should we regard such common sense as a reliable source of *correct* belief regarding idealism and realism? Russell excludes from his ground for realism common sense influenced by philosophy or theology.

On what ground may one recommend that common-sense beliefs uninfluenced by philosophy or theology are reliable or any more reliable than other commonsense beliefs? Commonsense beliefs influenced by certain kinds of physics, chemistry, biology, astronomy, sociology, psychology, or politics, for example, can be just as unreliable as commonsense beliefs influenced by certain kinds of philosophy or theology. A popular belief uninfluenced by philosophy or theology could still be highly unreliable owing to influence from other sources: for example, prejudicial political views.

The commonsense epistemology of Russell rests on *empiricism*: the view that the empirical input of the senses (e.g., visual, auditory, tactile, or gustatory experiences) is evidence appropriate to genuine knowledge. Russell sides with such empiricists as Locke, Berkeley, and Hume, against the rationalist view that a priori knowledge—knowledge independent of specific experience—can provide knowledge of what actually exists. Russell sides with such rationalists as Descartes and Leibniz, however, on the view that logical principles, whether deductive or inductive, are not known on the basis of evidence from experience. All evidence from experience, Russell claims, *presupposes* logical principles. Russell does allow, though, that our knowledge of logical principles is elicited or caused by experience. He thus permits a distinction between the *evidence* and the *cause* of a belief. In sum, Russell holds that “all knowledge which asserts existence is empirical, and the only a priori knowledge concerning existence is hypothetical, giving connections among things that exist or may exist, but not giving actual existence.”^[26] Russell’s empiricist epistemology is thus moderate, allowing for some a priori knowledge.

Russell^[25,26] distinguishes between knowledge *by acquaintance* and knowledge *by description*, and between knowledge of *things* and knowledge of *true propositions*. Knowledge of things can be either knowledge of things by acquaintance or knowledge of things by description. Knowledge by description requires knowledge of a true

proposition: knowledge *that* something is the case. Knowledge by acquaintance, in contrast, consists of direct non-propositional awareness of something, not of knowledge of truths. Russell holds that “to say that *S* has acquaintance with *O* is essentially the same thing as to say that *O* is presented to *S*.”^[25] Russell would say that readers are acquainted with the color of these printed words as they read them.

Russell’s epistemology attributes decisive epistemological significance to the natural sciences, so much so that the sciences are given epistemological priority over common sense. Russell acknowledges that the sciences begin with commonsense notions, such as notions of causation, space, time, and things, but that the sciences often need to revise or to eliminate such common notions to achieve their explanatory purposes. Russell observes that we typically start our theorizing from “naive realism,” the view that things are as they seem. We initially think that the objects we perceive really are as they appear to us: that pomegranates are red, that ice is cold, and so on. The natural sciences, however, offer a strikingly different view of the objects we perceive, a view entailing that the features ascribed to external objects by naive realism do not really inhere in the external objects themselves. Russell thus remarks that “naive realism leads to physics, and physics, if true, shows that naive realism is false.”^[28]

Philosophy, according to Russell, serves an important purpose, because it identifies how fundamental commonsense notions can be reconstructed to benefit the explanatory aims of the sciences. Russell denies, however, that philosophy offers a kind of knowledge ultimately different from scientific knowledge. He holds that “philosophy involves a criticism of scientific knowledge, not from a point of view ultimately different from that of science, but from a point of view less concerned with details and more concerned with the harmony of the whole body of special sciences.”^[27]

Why, however, should we take science as our final epistemological authority? This question will be especially urgent for people inclined to skepticism about the reliability of science. Russell offers little by way of reply: “For my part, I assume that science is broadly speaking true.... But against the thoroughgoing sceptic I can advance no argument except that I do not believe him to be sincere.”^[31] This reply will probably convince nobody with any cognitive caution. Russell understands the *truth* of statements as their describing *facts* that may be objective in that they transcend experience.^[28,30] He gives no reason, however, for thinking that everyone doubtful of science’s providing such truth is insincere. Epistemologists, among others, have long debated whether perception, memory, and the procedures of the natural sciences deliver objective truths. We cannot cogently settle this debate by assuming that beliefs based on perception, memory, or the sciences are broadly true, and that people doubting this assumption are insincere.

Russell's epistemology will not be helped here by the classical pragmatist view of William James (1842–1910), John Dewey (1859–1952), and C. I. Lewis (1883–1965) that knowledge has an unavoidable pragmatic component, viz., an element of “active interpretation.” Often we do seek a pragmatic rationale for a manner of interpretation: we then wonder about the practical consequences of wielding certain concepts (or, ways of classifying), relative to our explanatory purposes. Such a pragmatic rationale concerns the instrumental effectiveness of certain concepts in achieving our theoretical purposes, whatever those purposes happen to be. Traditional epistemologists, however, have wondered whether we can assess concepts relative to something more objective and less variable, viz., relative to the reliability of their portrayal of the objective, conceiver-independent world. Some philosophers hold that the latter kind of assessment, in terms of objective reliability, is distinctively “epistemological,” and that a merely pragmatic rationale can be, and often is, irrelevant to such epistemological assessment. They assume that epistemological assessment is centrally concerned with objective, purpose-independent truth, and reliable indications of such truth. Pragmatic success can sometimes proceed with beliefs that are unreliable and even false, such as when it is convenient for our (theoretical) purposes to maintain an unreliable, false view on something.

Given a coherent notion of objective, purpose-independent correctness, we can distinguish epistemological from pragmatic assessment. A notion of purpose-independent correctness allows that the concepts we use in theorizing often depend on our purposes in theorizing. A key issue, however, is whether it makes sense to talk of the purpose-independent correctness of concepts. A critic of pragmatism will suggest that the external world is featured in certain mind-independent ways (e.g., many of its objects have “natural” boundaries), and that our classificatory concepts can be more or less accurate, or reliable, in how they “fit” the mind-independent features of the external world. Given such coherent talk of accurate fitting, we can raise a distinctively epistemological issue about whether we know that our concepts accurately fit the external world. This issue drives much of traditional epistemology, and raises a skeptical problem noted in this entry's concluding section.

EXPLAINING EPISTEMIC JUSTIFICATION

According to the “standard analysis” of knowledge suggested in Plato's *Theaetetus*, we know that *P* if and only if we have a *justified* true belief that *P*. We might believe a true groundless guess (say, about the winning horse at the track), but would not thereby *know* that this guess is true. On the traditional analysis, knowledge requires not only that a belief condition and a truth

condition be satisfied, but also that the satisfaction of the belief condition be *suitably related* to the satisfaction of the truth condition. The latter requirement leads to a justification condition for knowledge, a condition that excludes such coincidental phenomena as lucky guesswork.

Contemporary epistemologists have given careful attention to the defining and explanatory conditions for *epistemic* justification, the kind of justification appropriate to knowledge. They typically have allowed for justified false beliefs, and this allowance is called *fallibilism* about justification. Fallibilism allows, for example, that the Ptolemaic astronomers before Copernicus were justified in holding their geocentric model of the universe, even though it turned out later to be a false model. In addition, justification for a proposition, according to most contemporary epistemologists, need not logically entail the proposition justified: It need not be such that necessarily if the justifying proposition is true, then the justified proposition is true too. When justification does logically entail what it justifies, we have *deductive* justification. *Inductive* justification, in contrast, does not logically entail what it justifies; it rather is such that if the justifying proposition is true, then the justified proposition is, to some extent, *probably* true. Contemporary epistemologists do not share a single account of the kind of probability appropriate to inductive justification. Most contemporary epistemologists agree, however, that epistemic justification is *defeasible*, that a justifying proposition can cease to be justifying for a person when that person acquires additional justification. For instance, one's justification for thinking that there is a pool of water on the road ahead can be defeated by new evidence one acquires upon approaching the relevant spot on the road.

A major topic of controversy in contemporary epistemology concerns the kind of justification we have for our beliefs about the external world, including the belief that conceiver-independent physical objects exist. Most contemporary epistemologists hold that such beliefs are justified only inductively, in terms of justification that does not logically entail the beliefs justified. Some skeptics, doubting that we have epistemic justification for the belief that external objects exist, have required deductive support for that belief; others have questioned whether we can even have inductive, probabilistic justification here. Epistemologists have no consensus here; nor is consensus anywhere in sight.

Some skeptics have used a *regress argument* to contend that we are not justified in believing anything about the external, conceiver-independent world (see Oakley^[22]). This argument stems from the question whether, and if so how, we are justified in holding any belief about the external world *on the basis of other beliefs*, that is, on the basis of *inferential* justification. A skeptic's use of the regress argument aims to show that each of the available accounts of inferential justification fails, and thus that such

justification is not to be had. The initial skeptical worry is: if our belief that external objects exist is supposedly justified on the basis of another belief, how is the latter, allegedly justifying belief itself justified? Is it justified by a further belief? If so, how is the latter belief itself justified? We seem to be threatened by an endless regress of required justifying beliefs, a regress that seems too complex to employ in our actual everyday reasoning or information gathering. Our options, according to many contemporary epistemologists, are straightforward. Either 1) explain how an endless regress of required justifying beliefs is not actually troublesome; 2) show how we can terminate the threatening regress; or 3) accept the skeptical conclusion that inferential justification is impossible.

A simple example illustrates the problem of inferential justification. While walking along the base of the highest mountain in Oregon, Mount Hood, we decide that a climb would be enjoyable, but that the current dangers of a snowstorm are too great. Our belief that mountain climbing today is dangerous is supported by other beliefs we have. We believe, for example, that (a) local meteorologists have predicted blizzard conditions today on Mt. Hood, (b) there is foreboding cloud cover overhead, and (c) the meteorologists' reports and the presence of the foreboding clouds are reliable indicators of an impending snowstorm. Our belief that mountain climbing today is dangerous receives support from our belief that (a), (b), and (c) are true. What, however, supports (a), (b), and (c) for us? Other beliefs we have will naturally contribute support here, and thus the chain of inferential justification will continue. Part of our support for (a) might be our belief that (d) we have seen internet reports today from some local meteorologists; and part of our support for (b) might be our belief that (e) we see foreboding cloud cover overhead. Our support for (d) and (e) might be similarly inferential, and thus extend the chain of inferential justification further.

Nonskeptical epistemologists have offered two noteworthy replies to the regress problem concerning inferential justification. One reply is *epistemic coherentism*: the view that all justification is inferential and systematic in virtue of "coherence relations" among beliefs. Justification for any belief, according to epistemic coherentism, ends in a system or network of beliefs with which the justified belief coheres. We should not confuse a coherence theory of *justification*, epistemic coherentism, with a coherence theory of *truth*. A coherence theory of truth, of the sort endorsed by Brand Blanshard,^[1] aims to specify the meaning of "truth," or the essential nature of truth; a coherence theory of justification aims to explain the nature not of truth, but of the kind of justification appropriate to knowledge. Recent advocates of epistemic coherentism, of one version or another, include Wilfrid Sellars,^[32–34] Nicholas Rescher,^[23,24] Gilbert Harman,^[11,12] Keith Lehrer,^[13,14] and Laurence Bonjour.^[3]

Advocates of epistemic coherentism have tried to answer two pressing questions. First, what kind of

coherence relation is crucial to justified belief? Second, what kind of belief-system must a justified belief cohere with? Regarding the first question, many proponents of epistemic coherentism acknowledge logical entailment and explanation as coherence relations among beliefs. Explanatory coherence relations are instantiated when some of one's beliefs effectively explain why some other of one's beliefs are true. For example, my belief that it is snowing outside might effectively explain the truth of my belief that my office windows are wet. Regarding the second question, not just any belief-system will serve the purpose of epistemic coherentism. Some belief-systems, such as those consisting of science-fiction propositions, seem obviously erroneous, and thus seem unable to provide a basis for epistemically justified belief. However one answers the previous two questions; epistemic coherentism implies that the justification of any belief depends on that belief's coherence relations to other beliefs. Such coherentism suggests that justified belief is systematic, given that it emphasizes the role of interconnectedness of beliefs in epistemic justification.

Skeptics will ask why we should regard coherence among one's beliefs as a reliable indication of empirical truth, of how things actually are in the empirical world. Consider, in addition, the following so-called *isolation objection* to epistemic coherentism: Epistemic coherentism entails that one can be epistemically justified in accepting a contingent empirical proposition that is incompatible with, or at least improbable, given one's total empirical evidence.^[17–19] A proponent of this objection does not restrict empirical evidence to empirical propositions believed or accepted by a person.

The isolation objection becomes directly applicable to coherence theories of justification once we expand the scope of empirical evidence beyond the propositions (or, judgments) believed or accepted by a person. Suppose, for example, that one's empirical evidence includes the subjective nonpropositional contents (e.g., visual images) of one's *nonbelief* perceptual and sensory awareness-states, such as one's seeming to perceive something or one's feeling a pain. Such contents, being nonpropositional, are not among what one believes or accepts. One might, of course, accept *that one is having* a particular visual image, but this does not mean that the image itself is a proposition one accepts. If we include the nonpropositional contents of nonbelief perceptual and sensory states in one's empirical evidence, the isolation objection will bear directly on coherence theories of justification. Coherence theories, by definition, make epistemic justification depend just on coherence relations among propositions one believes or accepts. They thus neglect the evidential significance of the nonpropositional contents of nonbelief perceptual and sensory states. Proponents of epistemic coherentism have not yet achieved a uniform resolution of the problem raised by the isolation objection.

A second nonskeptical reply to the regress problem is *epistemic foundationalism*, the view that epistemic justification has a two-tier structure: some instances of justification are noninferential, or foundational, and all other instances of justification are inferential, or nonfoundational, in that they derive ultimately from foundational justification. This structural view was outlined in Aristotle's *Posterior Analytics* (as a view about knowledge), and it received an extreme formulation in Descartes' *Meditations*. It is also represented, in one form or another, in the twentieth-century epistemological works of Bertrand Russell,^[28] C. I. Lewis,^[15,16] and Roderick Chisholm,^[4,5,7] among many others.

Versions of foundationalism about justification differ on two matters: the explanation of noninferential, foundational justification, and the explanation of how justification can be transmitted from foundational beliefs to nonfoundational beliefs. Some philosophers, following Descartes, have assumed that foundational beliefs must be *certain* (e.g., indubitable or infallible). Such an assumption underlies *radical* foundationalism, a view requiring not only that foundational beliefs be certain, but also that such beliefs guarantee the certainty of the nonfoundational beliefs they support. Two considerations explain why radical foundationalism attracts very few epistemologists. First, very few, if any, of our perceptual beliefs are certain; and, second, the beliefs that might be candidates for certainty (e.g., the belief that I am thinking) are insufficiently informative to guarantee the certainty of our highly specific inferential beliefs concerning the external world (e.g., beliefs suitable to physics, chemistry, biology, and astronomy).

Most contemporary foundationalists accept *modest* foundationalism, the view that foundational beliefs need not possess or provide certainty, and need not deductively support justified nonfoundational beliefs. Foundationalists typically characterize a *noninferentially justified, foundational* belief as a belief whose epistemic *justification* does not derive from other beliefs, but they leave open whether the *causal* basis of foundational beliefs includes other beliefs. Further, they typically hold that foundationalism is an account of a belief's (or a proposition's) *having* justification for a person, not of one's *showing* that a belief has justification or is true.

Modest foundationalists can choose from three influential approaches to noninferential, foundational justification: (1) self-justification; (2) justification by nonbelief, nonpropositional experiences; and (3) justification by a reliable nonbelief origin of a belief. Recent proponents of self-justification have included Roderick Chisholm^[4] and C. J. Ducasse.^[9] They contend that a foundational belief can justify itself, apart from any evidential support from something else. In contrast, proponents of foundational justification by nonbelief experiences avoid commitment to literal self-justification. They hold, following C. I. Lewis,^[15,16] that foundational perceptual beliefs can be

justified by nonbelief sensory or perceptual experiences (e.g., my nonbelief experience involving seeming to see a rectangular screen) that either make true, are best explained by, or otherwise support those foundational beliefs (e.g., the belief that there is, or at least appears to be, a rectangular screen here). Proponents of foundational justification by reliable origins hold that noninferential justification depends on nonbelief belief-forming processes (e.g., perception, memory, introspection) that are truth-conducive to some extent, in virtue of tending to produce true rather than false beliefs. The latter view invokes the reliability of a belief's nonbelief origin, whereas the previous view invokes the particular sensory or perceptual experiences that underlie a foundational belief. Despite the disagreement here, proponents of modest foundationalism typically agree that noninferential justification, at least in most cases, can be defeated upon expansion of one's justified beliefs. The justification for our belief that there is a blue screen before us, for example, might be defeated by the introduction of new evidence that there is a bright blue light shining on the screen.

Foundationalists must explain not only the conditions for noninferential justification, but also how justification is transmitted from foundational beliefs to inferentially justified, nonfoundational beliefs. Modest foundationalists, unlike radical foundationalists, allow for nondeductive, merely probabilistic connections that transmit justification. They have not, however, reached agreement on the exact nature of such connections. Some modest foundationalists hold that some kind of "inference to a best explanation" can account for transmission of justification in many cases. For example, the belief that there is a computer screen before us can, in certain circumstances, provide a best explanation of various foundational beliefs about our perceptual inputs. This, however, is a controversial matter among epistemologists.

A special problem threatens versions of foundationalism that restrict noninferential justification to subjective beliefs about what one *seems* to see, hear, feel, smell, and taste. Those versions must explain how such subjective beliefs can provide justification for beliefs about conceiver-independent physical objects. Clearly, such subjective beliefs do not logically entail beliefs about physical objects. Since extensive hallucination is always possible, it is always possible that one's subjective beliefs are true while the relevant beliefs about physical objects are false. Perhaps a foundationalist, following Chisholm^[5] and Cornman,^[8] can invoke a set of nondeductive relations to explain how subjective beliefs can justify beliefs about physical objects. This remains, however, as a challenge, since no set of such relations has attracted widespread acceptance from foundationalists. We should note, though, that some versions of foundationalism allow for the noninferential justification of beliefs about physical objects, and thus avoid the problem at hand.

In sum, then, the regress problem for inferential justification has a troublesome resilience about it. Coherentism and foundationalism, may provide a viable solution to the problem, but only after a resolution of the problems noted above. Let us turn briefly now to some complications facing the scope of knowledge.

SKEPTICISM

Epistemologists have long debated the scope of human knowledge. The more restricted we take the scope of knowledge to be, the more skeptical we are. Two influential types of skepticism are *knowledge*-skepticism and *justification*-skepticism. Unrestricted knowledge-skepticism implies that no one knows anything, and unrestricted justification-skepticism implies the more extreme view that no one is even justified in believing anything. Some forms of skepticism are stronger than others. Knowledge-skepticism in its strongest form implies that it is *impossible* for anyone to know anything. A weaker form would deny the *actuality* of our having knowledge, but leave open its possibility. Many skeptics have restricted their skepticism to a particular domain of supposed knowledge: for example, knowledge of the external world, knowledge of other minds, knowledge of the past or the future, or knowledge of non-empirical items. Limited skepticism is more common than unrestricted skepticism in the history of epistemology.

Arguments supporting skepticism take many different forms. One of the most difficult is *the problem of the criterion*, a version of which comes from the sixteenth-century skeptic Michel de Montaigne:

To adjudicate [between the true and the false] among the appearances of things, we need to have a distinguishing method; to validate this method, we need to have a justifying argument; but to validate this justifying argument, we need the very method at issue. And there we are, going round on the wheel.

This line of skeptical argument originated in ancient Greece, with epistemology itself (see Sextus Empiricus, *Outlines of Pyrrhonism*, Book II). It forces us to face these questions: how can we specify *what* we know without having specified *how* we know, and how can we specify *how* we know without having specified *what* we know? Is there any reasonable way out of this threatening circle? This is one of the most difficult epistemological problems, and a defensible epistemology must offer a plausible solution to it. Contemporary epistemology still lacks a widely accepted reply to this urgent problem. One influential reply from Roderick Chisholm^[6] rules out skepticism from the start, with the assumption that we do know some specific propositions about the external world. Chisholm endorses a *particularist* reply that begins with an answer

to the question of what we know. Such a reply seems, however, to beg a key question against the skeptic. A *methodist* (not to be confused with Christian Methodists) reply to the problem of the criterion begins with an answer to the question of how we know. Such a reply risks divorcing knowledge from our considered judgments about particular cases of knowledge. It also must avoid begging key questions raised by skeptics.

Cognitively relevant access to *anything* by us humans depends on such belief-forming, or information-gathering, processes as perception, introspection, judgment, memory, testimony, intuition, and common sense. Such processes, however, are subject to skeptical question regarding their reliability, and cannot themselves deliver non-questionbegging support for their own reliability. Put bluntly, we cannot assume a position independent of our own cognitively relevant processes to deliver a non-questionbegging indication of the reliability of those processes. This seems to be the human cognitive predicament; and nobody has yet shown how we can escape it. This, too, is a straightforward consideration favoring the conclusion that we must take skepticism quite seriously.

Questions under dispute in a philosophical context cannot attract non-questionbegging answers from mere *presumption* of the correctness of a disputed answer. If we allow such questionbegging in general, we can support *any* disputed position we prefer. We may then simply beg the key question in any dispute regarding the preferred position. Given that strategy, argument becomes superfluous in the way circular argument is typically pointless. Questionbegging strategies promote an undesirable arbitrariness in philosophical debate. They are thus rationally inconclusive relative to the questions under dispute.

Our question about the reliability of our belief-forming, or information-gathering, processes should be coherent. For instance, we should not demand non-questionbegging evidence indicating the reliability of vision, for example, while we call into question, and thus refuse, *any available evidence* indicating the reliability of belief-forming processes. That would be to demand that we stand somewhere to assess reliability while we are not allowed to stand anywhere at all. Such a demand would undermine itself in virtue of a kind of incoherence: *demand incoherence*. One *can* coherently question the reliability of all evidence available to us, and some skeptics do just this. In that case, however, one *cannot* coherently demand that we supply non-questionbegging evidence indicating the reliability of our belief-forming processes. If *all* available evidence, including that from any of our belief-forming processes, is under question, then *no* evidence will be non-questionbegging. As a result, a demand for non-questionbegging evidence cannot coherently include *unrestricted* questioning of all available evidence. Any demand, then, that we establish the reliability of our belief-forming processes must allow that some evidence

not be under question regarding reliability. Otherwise, a kind of incoherence threatens.

Arguably, we have a firm place to stand in answering questions about evidence and reasonable belief: we may stand firmly on our semantic, concept-forming intentions that give meaning to our terms. Consider the term “epistemic reason.” Philosophers of different outlooks share the general notion of an epistemic reason as a (*possibly fallible*) *truth-indicator*. An epistemic reason for a belief thus indicates, perhaps with only a degree of probability, that the belief is true. Our meaning-forming intentions to use terms in a certain way give semantic content to our talk of an “epistemic reason for a belief.”

We may form a settled semantic intention to use “truth-indicator” and “epistemic reason” as follows: a visual experience, for example, of an *apparent* pomegranate in a situation with no accessible contrary evidence is a (fallible) truth-indicator and thus an epistemic reason for a visual belief that an actual pomegranate exists. This semantic intention, owing to its meaning-conferring role for us, could then serve as a directly accessible semantic truth-maker for our ascription of an epistemic reason for a visual belief that an actual pomegranate exists. It would then be *part of what we mean* by “epistemic reason” that *such* an ascription captures an epistemic reason for a visual belief that an actual pomegranate exists. Our semantic intentions concerning “epistemic reasons” may thus serve as ultimate, even if revisable, truth-makers for ascriptions of an epistemic reason.

Skeptics might object that our semantic intentions can be “mistaken,” say in virtue of failing to capture language-independent justification. We can sidestep such an objection, however, because reality (the objective world) does not settle how *in particular* we must seek truth. For better or worse, it does not settle *which specific variant* (or specific concept) of justification, warrant, or knowledge is binding on a truth-seeker. Even so, a person seeking to acquire truth and to avoid error should accommodate any necessary conditions for truth-acquisition (e.g., logical consistency in a belief) and for reliable and warranted belief.

Skeptics cannot convincingly hold nonskeptics to a specific concept or strategy of truth-acquisition that recommends skepticism. In particular, skeptics cannot cogently require an epistemic concept or strategy for us that undermines the aforementioned kind of epistemic reason (for visual beliefs) grounded in semantic intentions regarding “epistemic reason.” A problem here for skeptics is that the aforementioned kind of epistemic reason is, so far as we can tell, at least as effective for judicious truth-acquisition as anything skeptics offer. In addition, skeptics lack firm footing to propose that such a semantically grounded epistemic reason is defective as a fallible truth-indicator.

Skeptics cannot plausibly charge us with question begging or circular reasoning here. It is *part of what we mean*

by “epistemic reason” that the kind of ascription in question captures an epistemic reason for a visual belief that an actual pomegranate exists. So, we may now shift the burden of argument to the skeptic, and call this *the skeptic’s burden*. We have produced a skeptic-resistant truth-indicator grounded in cognitively significant semantic intentions. We have also challenged skeptics, among others, to avoid demand incoherence. The skeptic’s burden is now *properly* the skeptic’s. Until this burden is met, we may endorse the reasonableness of some of the beliefs delivered by our belief-forming processes. We may even endorse the reasonableness of belief in the reliability of some of our belief-forming processes.

Traditional epistemology began with skeptical questions in ancient Greece, and contemporary epistemology must face similar questions. In facing skeptical questions, we can learn much about epistemology and its quest to explain the nature, origin, and scope of human knowledge. We can also improve our understanding of well-founded information gathering.

CONCLUSION

Epistemology, as the philosophical study of knowledge, will be valuable as long as knowledge is valuable. When pursued aright, it illuminates the nature, sources, and limits of knowledge. In doing so, it contributes to a critically important area of human understanding. Clearly, this discipline will not run out of controversy and difficulty in its important explanatory pursuits.

Ethical and Legal Aspects of Archival Services

Sara S. Hodson

Huntington Library, San Marino, California, U.S.A.

Abstract

Archivists deal with legal and ethical issues every day in the course of administering collections of personal papers. This entry will discuss legal and ethical aspects of archival services in three areas: acquisitions, access, and terms of use, in the context of research libraries and manuscript repositories. It will not deal with government, corporate, or institutional archives.

INTRODUCTION

Archivists who work in government or institutional archives oversee the noncurrent records generated by their organization. Other archivists, sometimes called curators or manuscript librarians, who work in libraries or manuscript repositories, administer collections of personal papers or organizational records that have been acquired from the outside, either by gift or by purchase. Both types of archivists face a variety of legal and ethical challenges as they oversee the materials entrusted to their care, and, despite the helpful codes of ethics compiled by the library and archival professions, these challenges often require archivists to make difficult decisions for which there is insufficient guidance. In one article, there is not sufficient space to treat adequately all types of archival settings, so this entry will discuss the legal and ethical issues that archivists must deal with for collections of personal papers.

The legal and ethical issues they face often fall within three broad areas of archival enterprise: acquisitions, access, and terms of use. The area of acquisitions encompasses both gifts and purchases of archival material, and includes such legal issues as the establishment and transfer of clear title, legal documentation of the terms of a transfer, and establishing fair market value. Ethical aspects of acquisitions include the courtesies of working with dealers, donors, and sister institutions.

The second area—access—consists of making research material available according to fair and equitable policies and procedures, within the guidelines of one's institution. For government archives, security and freedom of information determine access, and for institutional and organizational archives, access might be governed by the presence of sensitive or proprietary information in the records. For collections of personal papers, with which this entry is concerned, questions of access often revolve around the question of privacy and confidentiality.

The third legal and ethical area relates to terms of use. This generally pertains to copyright restrictions, literary

rights, and fees for publication or reproduction from original material.

ACQUISITIONS

In libraries and manuscript repositories, archivists acquire material by both gift and purchase from individuals or organizations outside their own institution, rather than by transfer from within the institution. This material may consist of collections of personal papers relating to prominent people, or they may be the records of an organization that are transferred to the repository for long-term safe-keeping. Certain legal considerations apply to such acquisitions, for both gifts and purchases.

First, the archivist must try to determine whether the donor or seller has clear title to the material and therefore has the right to transfer it to the repository. A certain degree of trust must obviously apply to such transactions, but the archivist should explore with the donor or seller the ownership of the material, albeit with delicacy and finesse. The best approach is to ask questions of the donor/seller, to learn as much as possible about the ownership and other history of the material. Such information is enormously useful in any event, to provide intellectual and historical context for the material, but it can also provide valuable clues as to the legal status of its ownership. For example, the donor/seller might recount a story of the papers turning up in a trunk in the attic or garage, or being held in safe deposit boxes by successive family members, or she might tell of holding onto the records of her activist organization in her den until the bulk reached a proportion she couldn't handle any longer.

Stories like these, when they appear plausible and straightforward, generally tend to indicate that ownership is not in doubt. The key for archivists, though, is to ask questions and to listen carefully. Equally important, archivists should trust their instincts. If something sounds wrong, it may well be wrong. The biggest danger signals of all are donors or sellers (the latter, especially) who say

they obtained their items at a swap meet or on eBay, for example. The rise of online auction sites has increased the opportunities and the motivations for the sale of stolen goods and, as a result, archivists must examine especially carefully all items that are offered for sale by an individual who either cites an online auction as his/her source or recounts a suspect story about the provenance, i.e., the ownership history.

Once the archivist is satisfied that the seller or donor has clear legal title, and that there is no other joint owner lurking in the wings, and if the material on offer fits the institution's collecting policy, the next step is to prepare a deed of gift or of sale setting forth the terms of transferring the material to the repository. Such documents are essential, but they have not always been employed by institutions acquiring manuscripts or other rare material.^[1] For more than half the twentieth century, curators or archivists simply relied on a handshake to seal a transaction. This practice, however, fell out of use during the 1960s, once its obvious failings were recognized, and when archivists increasingly had to deal with the aftermath of undocumented gifts, in the form of donors suddenly appearing to reclaim collections for which institutions had no paperwork to prove ownership.

Deeds of gift and of sale may be quite simple or more elaborate, depending on the institution's preference and on the needs of each transaction. The basic elements include the date, the name, address and phone number of the donor/seller, the conditions of transfer (sale price, for example, and the transfer or retention of copyright or literary rights), a description of the papers being transferred, a note about the disposition of duplicate or undesired material, and a note about any restrictions on the use of the papers, e.g., identification of items to be sealed for privacy reasons. The document should be signed by the donor/seller and by the archivist or other representative of the repository, and each party should receive a copy.^[2,3]

A similar document is a deed of deposit, which sets forth terms under which a repository accepts material not as a permanent acquisition but on temporary deposit. Deposits often become gifts, but archivists should accept deposits only with the greatest care. The deed of deposit must fully outline the terms of the deposit, leaving nothing to chance and nothing as merely an understanding. Archivists should take care not to accept open-ended deposits, i.e., having no terminal date. Open-ended deposits can hold an archivist hostage, subject to the demands of the depositor, with no end in sight. It is far preferable to state an end-date, by which time the collection is to be kept by the repository or returned to the depositor. Also, the deed of deposit should indicate whether the depositor will pay the cost of processing and housing the collection if he or she reclaims it. The amount of these costs should be clearly spelled out.

For either sale or gift transactions, it may be advisable or necessary to have the material's fair market value

determined by an outside appraiser. With sale situations, it is better for an objective, outside appraiser to establish a fair price for material than for either the seller or purchaser to set a price. Both of the parties involved in the transaction have agendas, the seller to gain the maximum return for the material, and the purchasing repository to spend as little money as possible. Only an outside party, in the form of a qualified appraiser, can approach the situation with the necessary objectivity. There are rare book and manuscript dealers nationwide who know the market and can perform appraisals for a fee. Dealers and appraisers often specialize in particular formats (manuscripts, books, or photographs, for example) or subjects (literature or western history, for example), so archivists do well to locate an appraiser who specializes in the type of material at hand, in order to secure the best possible appraisal. Most but not all dealers are members of the Antiquarian Booksellers of America (ABAA), an organization that sets forth its own code of ethics to which its members are expected to adhere.^[4] When engaging an appraiser, the archivist or seller should ascertain what the fee will be and should avoid anyone who sets a fee that is a percentage of the appraised value of the material, a clear conflict of interest.

Appraisals are required in gift situations, if the donor wishes to take a tax deduction for the appraised value of the papers. As with sale situations, the appraisal should never be performed by a party holding interest in the transaction but always by an objective outsider. An appraiser doing the work for a tax deductible gift will prepare a detailed appraisal report providing his or her credentials, a narrative about the material and about the market history of its value, and a list of the items and their fair market value. The question of who is to pay the fee should be discussed and agreed upon before the appraisal begins. Repositories' policies vary about the question of who pays an appraisal fee. Often, institutional policy requires that the donor pay for the appraisal, but some institutions stipulate that, if the institution pays the fee, then the donor must reduce his or her tax deduction by the amount of the appraisal fee. Archivists must learn the policy of their institution and should obtain legal advice if necessary.

There is one category of donation for which the donor can not obtain a tax deduction—self-generated papers. According to statute of the Internal Revenue Service (IRS), an individual who donates his or her own papers may take as a deduction only the value of the materials themselves, i.e., the paper or other surface, not of the text or art created on those materials. This came about when papers donated by former President Richard Nixon carried inflated market value, yielding a bountiful tax deduction. Since that time, donations by the creators of personal papers to repositories have declined, since the only incentive is altruistic, with no financial benefit.

In a cruel irony, family members, collectors, and others who have acquired an individual's creations may take a

full tax deduction for the market value of those creations. Thus, an author, composer, or artist cannot derive any real tax benefit for donating his/her own works, but others can. Moreover, the IRS has taken a strict construction of the code, deeming incoming correspondence, for example, as “self-generated” since it comes in response to letters sent by the creator of the papers. This means that a creator cannot receive a tax benefit from any part of his papers, even those parts written by others. In addition, the creator cannot give papers to a spouse or other family member in order to derive benefit. The IRS watches for such efforts to circumvent the tax code.

When papers are donated to a repository by someone other than its creator, and when the material holds sufficient fair market value, then the donor can receive a tax deduction for the appraised value. As in sale situations involving private sellers, an outside appraiser is engaged to evaluate the papers, and the appraiser writes a full report after examining the material. In addition to the report, the appraiser generates and signs an IRS 8283 form, which is then signed by the donor and the repository before the document becomes part of the donor’s tax filing.

Beyond the legal considerations surrounding gifts, purchases, and deposits, there are ethical aspects to the acquisition of archival material by libraries and manuscript repositories. With regard to purchases, archivists work with private sellers, manuscript dealers, and auction houses. With all three, archivists should proceed with honor and the highest of ethics. In working with private sellers, who may never have undertaken such a transaction before, archivists should never take advantage of the person’s inexperience. As already discussed, an outside appraisal should be secured in order to determine a fair purchase price.

When working with manuscript dealers, archivists should develop good relationships and behave with courtesy and consideration. Dealers are archivists’ allies and will often make referrals and contact archivists when appropriate material comes to them for resale or on consignment. In addition, dealers are often the first to learn of archival thefts, when a thief brings items to sell. Dealers know major library holdings and especially the collections of repositories in their geographic area, and they are likely to recognize stolen material when it comes in the door and to contact the repository that has suffered the theft. When archivists develop an ongoing relationship with a dealer, it is often possible to request that material be sent on approval, giving the archivist a chance to examine it before committing to purchase it. In such instances, it is crucial that the archivist treat this as a privilege and not abuse it, either by holding onto the material at length and then finally sending it back, or by treating material carelessly or damaging it before returning it.

In auctions, which are the most competitive of purchase situations, archivists must nonetheless proceed with integrity. Archivists often use agents to bid for them, especially when auctions take place a continent or half a world away.

An agent examines the items and reports to the archivist, who then issues clear, unambiguous bidding instructions. When engaging an agent, the archivist should ask questions about the agent’s fee and policies, to ensure a compatible working relationship. Archivists must avoid collusion with other individuals and must refrain from bidding on an item unless seriously interested in it. Occasionally, it is possible for an archivist to defer to a colleague from another repository, but this can be risky, since it involves delicate discussion about each repository’s intentions.

As with purchase situations, ethics come into play when archivists deal with donors, and, as with purchases, the fundamental principle is to behave honorably. Many donors have never been in this situation before, and they don’t know how to approach a repository or what to expect. It is incumbent on archivists to explain, fully and honestly, every step and aspect of the donation process, so the donor understands the choices and possibilities involved. Occasionally, donors will behave as though they don’t know much about the gift process, when in fact they have visited other libraries and are listening to see if an archivist’s explanation matches that heard elsewhere. Whether a donor has prior knowledge of the gift process or not, archivists must offer a straightforward, even selfless description of the gift situation. In working with donors who are family members, especially spouses or life partners, of a deceased creator of papers, the archivist should be especially patient and sensitive to the emotional wrench caused by parting with a collection. It is important to give donors time and space to say good-bye to material that is, to a great extent, the tangible representation of a beloved individual.

For purchases and gifts alike, archivists must be willing to refer collections to other libraries, if appropriate. A healthy spirit of competition among repositories is fine, but it must never become ruthless. Archivists must be willing to defer to their colleagues in other repositories when appropriate, no matter how much they might covet the material in question. The bottom line with acquisitions, and the higher ethic, is for archivists to ensure that collections go to the most appropriate home, wherever that might be. Therefore, archivists should know the holdings of other repositories and should pursue cordial relationships with their colleagues, in order to foster interinstitutional cooperation for the good of the materials they preserve.

ACCESS

Just as archivists must proceed fairly and impartially when acquiring manuscripts and archival collections, so must they provide access to their collections in a fair and equitable manner. In the past, and up to the 1960s, research libraries holding rare materials including archival collections, often granted to researchers exclusive access to certain collections and would then turn away other researchers seeking to use the same material. This practice led to the tying up of collections for years, and sometimes

decades, when researchers would hang on to their exclusive right of access like grim death, moving forward at a glacial rate while other researchers waited in frustration on the sidelines. A more recent instance of this kind of exclusive access occurred with the Dead Sea Scrolls, which, for several decades after their discovery in 1947, were available for research only among a small circle of “authorized” editors who closely guarded their own right of use and passed on that right to favored graduate students or other recipients. Other scholars seeking access to the Scrolls were turned away. Only in 1992 was this exclusive and exclusionary Scrolls cartel broken, when William A. Moffett, the library director at the Huntington Library, boldly opened the library’s set of Scroll photographs to all researchers, in contravention of explicit threats from the cartel of official editors.^[5]

In another dubious access practice that persisted in research institutions into the 1960s, many libraries allowed access to certain groups or categories of researchers, while denying it to others. In this kind of selective access, whose terms were often dictated by donors of collections, the use of manuscript material might be denied on the basis of religion, gender, or ethnic group. For example, one collection had long been closed to women and to people of British heritage. As soon as a new chief curator (a woman, and of British extraction) was appointed in the late 1960s, she quietly lifted this restriction. In another example, a collection had been off-limits to Jews, Catholics, and the donor’s nephew. Again, this unfair, inequitable, and onerous restriction was quietly lifted with a change in administration. By the late 1960s, research libraries began to abandon both types of restriction—the exclusive use for a given researcher, and the exclusion of certain people—in favor of fair and equitable access for all researchers.

Since the late 1960s, the most common way in which archival material might be restricted is for reasons of privacy and confidentiality.^[6] Repositories increasingly collect modern archival material, containing letters, diaries, and other material written by or referring to people still living. For this reason, archivists must be aware of privacy issues and of the possible presence of sensitive material in the collections they oversee. The Code of Ethics of the Society of American Archivists (SAA) includes this statement about privacy in archival collections: “Archivists protect the privacy rights of donors and individuals or groups who are the subject of records.” (The code also protects patron confidentiality, continuing: “They [archivists] respect all users’ right to privacy by maintaining the confidentiality of their research and protecting any personal information collected about them in accordance with the institution’s security procedures.”)^[7]

Typically, the sealing of items or files in an archival collection comes at the request of the donor of the collection, or as a result of discussion between the donor and the archivist. When material is sealed for reasons of privacy,

this restriction must apply to all people who use the collection. That is, it must not apply only to selected individuals or groups of people, and no exceptions should be made to the administration of the restriction.

Certain categories of data are protected by law and may not be seen by researchers under any circumstance. These categories include medical records, personnel records, student records, and attorney–client files. Archivists overseeing such materials must know the law regarding them and must ensure that they are never made available to researchers. Many repositories refrain from even acquiring these kinds of records, because they are so problematic.

For other archival material that falls outside these legal categories, the question of safeguarding privacy can be extremely difficult, especially when there is no directive from a donor or when there is no family member or other person in a position to advise the archivist about potentially sensitive material in a collection. In the absence of guidance from someone knowledgeable about a collection, an archivist who identifies sensitive items is faced with a tough challenge. It can be risky, and potentially improper, for an archivist to take upon himself or herself the responsibility of restricting private or sensitive material. Archivists tend to have a highly developed sense of ethics and therefore often worry about possibly violating the privacy of individuals represented in collections they oversee. However, they tread in dangerous territory when they begin to act on their own to seal manuscripts in order to protect the privacy of the individuals represented in the collections. To do so is a presumptuous act, and archivists who are tempted to take that action must examine their motives to ensure that they are not engaging in censorship. For example, an archivist might discover in a collection a series of recent letters that discuss someone’s sexual preference or reveal an abortion obtained without a husband’s knowledge. Should the archivist take on the responsibility of sealing such material, or should he or she avoid making such a difficult, even subjective judgment?

While the SAA Code of Ethics advises archivists to safeguard the privacy of those whose papers are entrusted to their care, it does not, and can not, provide specific advice about how to proceed in such challenging circumstances. Instead, archivists must navigate on their own the turbulent currents that roil the privacy/openness seas. Most institutions have policies for dealing with sensitive documents, and most of these policies land in the gray area somewhere between the extremes of sealing on a wide scale, on the one hand, and sealing nothing, on the other. One British library hewed to the restrictive end of the continuum, as a matter of policy sealing all letters written by individuals still living. This approach held the seemingly unassailable virtue of consistency, but for most Americans it was too draconian and it kept a vast amount of research material unavailable. At the other end of the continuum, some American repositories seal nothing,

asserting that their archivists are unqualified to make the difficult judgments required in restricting material. This approach also possesses the virtue of consistency, and it can ensure that a repository is unlikely to be held liable for breaching privacy since it seals nothing. Most repositories, however, land somewhere between these two practices, occupying the difficult gray area of restricting under some circumstances.

The difficulty of attempting to safeguard privacy in archival collections has been made even more problematic by virtue of the rise of the Internet and electronic files. The current trend toward digitizing archival documents and posting them on the Internet profoundly increases the potential risk to the privacy of those represented in the documents. Posting a private or confidential document on the Internet where millions of people might read it constitutes a far greater threat to privacy than is the case when a few researchers read that document in a library's reading room. In addition to the documents themselves, the finding aids that describe and catalog the documents in collections can breach privacy to a greater degree when they are posted online. For example, a collection of documents relating to a girls' reformatory can carry a note cautioning researchers in the reading room not to use the girls' names in publications. But, if the online finding aid includes a list of the files, by name, the girls' privacy would be violated. Thus, both for the collections themselves and for the catalog records and finding aids that provide access to those collections, archivists must stop and think about the privacy implications of posting on the Internet. This is not to assert that documents and finding aids in general should not be made available over the Internet, but just a cautionary note to be aware of privacy and confidentiality when determining which materials should be posted online.

TERMS OF USE

Once a research library has acquired a manuscript collection, by either gift or purchase, and when it is opened for research access, the archivist must begin to deal with the third general area of legal and ethical issues—copyright, literary rights, and the publication or other use of the material. For more than 200 years, the United States has had copyright statutes in place, granting authors, artists, composers, and other creators of original works the exclusive right to control, and benefit from, the publication, reproduction, and further use of their creations. Throughout this time, attorneys and other interested parties have struggled to balance creators' rights against the rights of others to quote from or use in part the works created.

The copyright act has changed over the years, and the basic provision of the current law provides copyright protection for the life of the author plus 70 years, although there are further provisions based on the date of creation

and whether a work is anonymous. The statute's provisions are strict and do not allow copying unless the archives owns the copyright. However, there are two special exceptions to the law. First, the doctrine of fair use (Section 107) allows copies of a copyrighted work to be made "for purposes such as criticism, comment, news reporting, teaching (including multiple copies for classroom use), scholarship, or research." Second, in order to assist libraries, archives, and scholars, Congress enacted Section 108, which allows an institution to copy certain works if the purpose is preservation, security, or replacement of the work. The allowance is complicated and holds certain conditions that an institution must meet in order to proceed within the guidelines of Section 108, so archivists would be well advised to consult the copyright law itself, as well as interpretive sources.

The single best source for details about the copyright law provisions and for helpful charts, including a "copyright decision tree," is the Copyright Information Center at Cornell University, and there are many other very useful sources for explanation and interpretation of the copyright law.^[8-10] It can be difficult to identify and locate the current owner of copyright, but a helpful Web site, called "WATCH: Writers, Artists and Their Copyright Holders" has been created and is maintained by the Harry Ransom Center at the University of Texas, Austin, in collaboration with the University of Reading Library. This site maintains a data base of copyright holders that can be searched by author, artist, or other creator name and that provides the name and contact information of the copyright holder.^[11]

Similar to copyright is the right of first publication of an unpublished, original creation. This right is known as the literary rights, and modern collections in particular often arrive in a repository carrying material whose literary rights are held by the creator or by his/her heirs. Donors or sellers of collections seldom are willing to transfer their literary rights to the repository, choosing instead to retain those rights in order to reap whatever profit might accrue to the publication or reproduction of the works. When receiving a new acquisition in which literary rights are at issue, the archivist should always ask about the rights and should inquire whether the donor, creator, or family would be willing to pass the rights to the institution, either immediately or eventually. The gift or sale document should describe fully the disposition of literary rights so the institution is fully informed and will be able to refer researchers to the holder of the rights in order to obtain permission to publish or reproduce.

Even though a library or repository might only occasionally receive either the copyright or literary rights along with the collection material, the institution does hold the physical property rights. When the material is given or sold to the repository, and the gift or sale document has been signed, the physical items themselves become the property of the institution. Thus, there are two forms of ownership of documentary material—the

copyright or literary rights, and the physical property rights—and these separate rights can be held simultaneously by different parties. Moreover, once a work has gone out of copyright, or once the literary rights are no longer an issue, the physical property rights still apply. This allows the owning repository to charge use fees to researchers, film makers, and others who wish to quote from, publish, or reproduce material from the repository's collections.

The question of whether libraries and archives should charge use fees holds some degree of controversy among library and archival professionals. Some feel that researchers and others wishing to use material, especially material in the public domain, should not have to pay any fee at all. Others feel that users should pay for the privilege of publishing or otherwise making use of unique material held in a repository. Among the institutions that charge use or publication fees, most use a graduating scale of fees, charging higher fees for commercial use and lower fees or no fees at all for scholarly or nonprofit use. This issue becomes more complicated with regard to material whose literary rights are held by an individual or estate that takes an active role in administering those rights. Archivists often go ahead with charging use fees when a literary rights holder is involved, but they may decide to defer to the literary rights holder, especially in cases when commercial use involves hefty payments to the literary rights holder.

CONCLUSION

As the foregoing discussion indicates, archivists must face many ethical and legal challenges every day, as they administer the collections entrusted to them. There can be many different types of legal and ethical dilemmas, but many fall within three areas: acquisitions, access to collections, and terms for the use of the collections. In these areas, and in all facets of their work, archivists must not only follow the laws that apply to archival enterprise, but they must also strive to hew to a high level of ethical

behavior. Although doing so will always be challenging since many situations fall within gray areas, archivists have many resources at hand to assist them in making the decisions that face them as they follow the codes and tenets of their profession.

Ethical Aspects of Library and Information Science

Richard Rubin

Thomas J. Froehlich

School of Library and Information Science, Kent State University, Kent, Ohio, U.S.A.

Abstract

This entry discusses many of the ethical considerations in the library and information science professions: collection development, censorship, privacy, reference services, copyright, administrative concerns, information access, technology-related issues, and problems with conflicting loyalties. It surveys the factors that affect ethical deliberations in the information professions: social utility, survival, social responsibility, and respect for individuality. It also looks at professional factors in ethical deliberations, such as professional codes of ethics, and the values that support ethical principles of professional conduct: truth, tolerance, individual liberty, justice and beauty. In the final section, it indicates the kinds of actions to promote ethical conduct at the organizational, professional and individual levels. As a final caveat, it indicates that ethical decisions require deliberation and reflection. While one can articulate values, factors, codes, and actions, they inform ethical reflection that must often confront and negotiate dilemmas and tensions.

INTRODUCTION

Many of the individuals who occupy our most important professions, such as politicians, lawyers, business executives, and bankers are given low marks for their ethics and honesty.^[1] A cursory glance at daily newspapers reveals religious leaders who have less than moral lifestyles, politicians who lie and benefit from the public purse, and businessmen who manipulate financial markets and unduly influence public policy.

Despite the general sense of ethical decline, the ethical dimensions of our personal and professional behavior are transparent in day-to-day activities. The actions we take everyday are reflexive in terms of ethical conduct; our days are not replete with ethical reflection. Rather, we operate with a subconscious ethical system, whether poorly or well developed, that emerges into consciousness only when a special event or situation makes us doubt or defend our judgments or actions. At these times individuals try to make explicit the values and beliefs that underlie their actions or judgments.

Consider what situations occur in the library and information workplace that create this type of ethical dissonance:

1. When we are about to lie to someone
 - a. Indicating that there is no problem when there is.
 - b. Giving someone a good performance review when he or she has performed poorly.
 - c. Lying about why a person did not get a job.
 - d. Reporting in sick when we are not sick.
 - e. Reporting or recording inaccurate data in business reports.
2. When we believe that we are about to do someone harm
 - a. Permitting a young person open access to Internet sites we feel could be psychologically harmful.
 - b. Disciplining or terminating an employee.
 - c. Violating an individual's privacy or disclosing a confidence.
 - d. Unobtrusive monitoring of a patrons Internet use.
3. When we believe we are about to receive something we did not deserve
 - a. Receiving too much money in our paycheck and not reporting it.
 - b. Receiving credit that someone else should have.
 - c. Misrepresenting the quality of our work.
4. When we deprive someone of information or ideas
 - a. Censoring or restricting library materials.
 - b. Withholding information from a fellow employee to encourage his or her failure.
 - c. Withholding information concerning the inadequacies of an information source or database.
5. When we are asked by someone in authority to act in an unlawful or unethical fashion
 - a. Falsifying or backdating a record to hide unlawful activity.
 - b. Being encouraged to misrepresent oneself to get information from an unknowing source.
 - c. Being asked to deceive others for the "best interests" of the organization.

Most individuals feel ethical qualms in these situations, and there is general agreement that there should be standards of conduct to limit unethical actions on the part of information workers. Buckley, for example, has proposed

that the “Golden Rule” has application in understanding our ethical obligations in reference work.^[2] In addition, ethical constraints apply not only to individuals but to organizations. Institutions, including libraries and other information organizations, are not value-neutral; they act, make choices, affect human beings, and receive, allocate, and disseminate resources in ways analogous to individuals. Many corporations and industries have recognized the importance of organizational and employee ethics, which often manifest themselves in ethical codes. Fleisher and Blenkhorn report that over 95% of all major corporations use ethical codes.^[3]

Some of the issues and values that underlie ethical action in libraries and other information organizations will be discussed below. Of course, such a brief exposition cannot cover all of the ethical issues and concerns involved in library and information service. This discussion is meant to provide a framework to help structure further ethical analysis. In addition, there are several other limitations:

1. First, there are many different types of library and information services. Not only are there different types of libraries (academic, public, school, and special), but the information services could include database searchers, information consultants, and chief information officers. Trying to find a common ethical basis for these many different types of information providers and administrators may not be possible. Although general ethical principles will be advanced in this discussion, specific types of information workers especially those in for-profit enterprises may not find the discussion completely relevant to their type of information work.
2. Second, the discussion presented is based primarily on Western ethical traditions. The ideas suggested or values advanced may not apply in the same way to other cultural traditions. For work on intercultural information ethics, see Capurro.^[4]
3. Third, this essay proposes one view of ethical conduct among information providers. Other views are possible; indeed, alternative perspectives should be encouraged so that diverse ethical dimensions can be exposed and analyzed.

MAJOR AREAS OF CONCERN: AN EXAMINATION OF THE LITERATURE

The library and information professions have recognized the ethical dimension of information work through irregular discussions in professional publications. The focus on ethics in librarianship and information science has become even sharper in the last few years, due to the growth of the Internet, the application of library and information skills to new domains related to the Internet, and the

convergence of information-related disciplines. In 1989, the University of Illinois, Graduate School of Library and Information Science, sponsored a conference on ethics.^[5] Since then, the body of ethical literature in the library profession has increased and the domain of concern has been enlarged to “information ethics” (see Smith^[6] for an overview and Froehlich^[7] for a brief history). The literature includes some writers who have attempted to identify specific factors that produce ethical friction, and who have advanced rules of conduct (e.g., Rubin^[8] and Baker^[9]).

The potential for ethical conflicts in library and information services is considerable. Among the major issues that have appeared in the literature are the following.

Selecting Materials and Censorship

Many selectors confront the unpleasant possibility that the selection of certain materials will cause controversy in the local community. Such controversy could generate considerable anger and negative publicity and jeopardize library budgets and the jobs of librarians. Similarly, the librarian may believe that certain materials actually have a harmful effect on patrons, most notably children. This belief might be supported by other members of the community. Ethical tensions are bound to arise in such circumstances. To what extent is refusal to select items justified because of the possibility of controversy in the community and the expectation that some materials may harm others? These problems are some of the many associated with ethical issues in acquisitions and censorship.^[10–14]

Privacy Issues

Privacy issues have grown in importance and have been of increased concerns to librarians and other information professionals especially since September 11th. As the powers of government have expanded in order to catch terrorists, so has the capacity of government to entrap innocents in the Net. With the passage of the USA Patriot Act, the new crime of “domestic terrorism” was created. The law expanded the power of government to issue wiretaps, obtain search warrants, and gather records that at earlier times were unavailable or required a court to determine probable cause.^[15] Today, such organizations as the American Library Association (ALA) express a need for constant vigilance to protect the rights of patrons to use new and traditional sources of information without unnecessary surveillance. The ALA has supported a variety of activities including supporting amendments to the USA Patriot Act, most notably the freedom to read protection act, to exempt libraries and bookstores from some of the more invasive aspects of the law.^[16] The ALA has also supported a variety of resolutions exhorting the need to protect citizens from undue intrusions on their privacy. These include the “Resolution Reaffirming the Principles of Intellectual Freedom in the Aftermath of Terrorist

Attacks,” and “Resolution on the USA Patriot Act and Related Measures That Infringe on the Rights of Library Users.”^[17,18]

Not only are libraries concerned with monitoring of Internet use or use of other electronic databases, but they are also concerned with more traditional records such as circulation records. Even if the Patriot Act did not exist, circulation records have been at the core of privacy issues in libraries for many years. Requests for such records have come from parents of children, police, prosecutors, courts, and the FBI.^[19] From the perspective of librarians, revealing such information would create a “chilling effect” on borrowers, who, if they believe their reading habits were made public, would subject them to embarrassment. Consequently, patrons would not take out certain books or have online searches conducted on some controversial topics if they felt they could be subjected to public scrutiny or the scrutiny of unsympathetic individuals.^[20] On the other hand, as a public institution, there are those who would argue that such records are public records, and the right of the citizenry to know what is happening in a public institution outweighs the privacy rights of individuals. Similarly, in circumstances in which a crime has been committed and the request for circulation records comes from law enforcement agencies and the courts, librarians also feel a public duty to cooperate with such agencies.

Another typical privacy issue relates to the age of the library user. For example, does a library user under the age of 18 have the right to privacy in terms of materials used, and does that right vary? For example, if a teenager takes a book out of a library, does the parent or guardian have a right to know the titles of those books, especially if there are fines on the material and the parent is responsible for the material? If a teenager has a right to privacy in the use of materials, what about a pre-teen—someone who is six or eight years old? What if the material is secured from a school library? Are there additional legal burdens in that case?^[21]

Privacy issues may also involve the monitoring of library users in regard to copyright violations or unlawful use of digital resources. On many occasions one may observe a patron making multiple copies of copyrighted material, or copying an entire book. Similarly, an individual may be observed accessing material that may be a violation of law, i.e., accessing child pornography. To what extent is the librarian ethically obligated to surveil and report such individuals, or, at the least, to warn the individual that such conduct is unlawful and to desist?^[22]

Reference Services

The fundamental tenet of reference service is to provide the information requested by the patron or client. Given the importance of this service, a variety of ethical questions arise, including the following:

1. To what extent does ability to pay for an information services raise ethical issues? Is it ethical to charge for certain types of reference services (e.g., online services) even if charging tends to discriminate against those who cannot afford the service?^[23,24]
2. Is it ethical to provide different levels of reference service? For example, is it proper to provide library board members or influential politicians quicker, better, and more comprehensive service than regular patrons?
3. Is it ethical to use support staff to answer reference questions that should be answered by degreed librarians?^[25]
4. Is it ethical to provide reduced time in the reference interview to a patron because the librarian is in a hurry to serve other patrons?
5. Is it ethical to limit information if you believe the information may harm the patron?
6. What is the degree to which an information provider should divulge the inadequacies of the information being provided or the information systems providing it?
7. What are the ethical limits for the information provider in obtaining information? For example, to what extent can the information provider deceive others to get information or invade other information systems without permission or without identifying their purpose?
8. To what extent can a librarian provide medical and legal reference services without giving the impression that legal or medical advice is being proffered?^[26–28]
9. To what extent is a reference librarian obligated to report school or college plagiarism or other student’s inappropriate use of the Internet to the appropriate educational authorities?
10. What is the obligation of a reference librarians to violate (interpret very liberally) a digital rights management contract that severely restricts use by librarians or patrons?

For additional issues related to reference services see Bunge,^[29] Katz and Fraley,^[30] and Ulvik and Salvesen.^[31]

Copyright Issues

Information activities generally require the use of print, nonprint, and electronic sources. The copying or transferring of such information is often a necessity. While a primary motivation of publishers and electronic database producers is the profit earned through sale or lease of their product, the motivation of many information providers, most notably librarians, is access to information for the patron at the lowest cost. An ethical tension arises when the information needed is difficult or impossible to obtain

efficiently without violating copyright restrictions. One's ethical feelings regarding obeying the law and respect for the rights of copyright owners conflicts with one's ethical obligation to provide the information. The issue is further complicated in the digital environment because of the concerns of electronic information providers concerned about excessive copyright abuse of their content. This has led to new treaties and laws including the WIPO treaty, the Digital Millennium Copyright Act, and the Teach Act—each attempting to balance the interests of the user or information intermediary (e.g., the librarian or information specialist) with the interest of the copyright owner. In addition, greater restrictions arise regarding electronic information because the providers of the digital information often require that a license be signed before access is provided. Such licenses may contain no "fair use" provision or right of first sale available under copyright law. This may prevent redistribution of useful content.^[22]

Administrative Issues

There are many opportunities for library managers and administrators to encounter ethical situations in the workplace. Oftentimes certain actions seem necessary in the organizational context, which, in other circumstances, might be problematic. Among the areas of ethical tension are the following:

1. Purposely withholding information.
2. Making deceptive statements, providing distorted or false information, or acting deceptively.
3. Violating the privacy of individuals, e.g., monitoring employee e-mails or use of the Internet.
4. Being motivated by personal likes, dislikes, anger, or desire for retribution when making a decision.
5. Being motivated by personal gain when making a decision.
6. Acting in a discriminatory fashion.

For issues related to library administration and personnel see Heim,^[32] Rubin,^[8] Baker,^[9] and Du Mont.^[33]

Issues of Access

Of considerable concern to librarians and other information professionals is free access to information. Is information access a privilege or a basic right? If it is a right, is it a right to all sorts of information (e.g., expensive online services) or to information bearing upon the basic needs of life (e.g., health, housing, governmental issues, etc.)?^[34] Arguments have been put forth for services for which a library could charge by Williams.^[35] Access issues have been aggravated because the costs to acquire, store, catalog, and retrieve materials have escalated, partly because of the rapid growth of information and partly because of the increasing need for and costs of technologies to cope

with this growth. Put another way, the new technological means for information storage and transmission exacerbate the differences of information "haves" and "have-nots" in the world. Is there an ethical obligation to equalize the differences? Also in the electronic environment, questions of monitoring access has arisen. This has become particularly sensitive with the passage of the Child Internet Protection Act which requires some type of Internet filtering in schools and public libraries that receive certain types of federal funds. The monitoring of patron use of materials and services generally raises concern over the "chilling effect" this may cause on the use of materials that may be considered useful but controversial. Hence librarians are placed in the position of enforcing a law which may inhibit individuals from finding the information they want and need.^[36] Other access issues concern access to data collected by various local, state, and federal agencies, such as through the Freedom of Information Act (FOIA). In the post-9/11 era, there have been significant restrictions of governmental information that was traditionally available. For example, information on water resources, electrical grids, or locations of power plants, or other aspects of the U.S. infrastructure may now be unavailable to the citizens who financially support them.^[15]

Cataloging issues may also be seen as issues of access; materials cataloged in various ways can either facilitate or pose a barrier to access. Ethical issues may arise for example when decisions are made regarding whether simplified or more complex cataloging rules are applied or whether to place materials in particular subject areas (where do creationist texts go—in religion or science?).^[37] For ethical issues and suggestions for a code of ethics for catalogers, see Bair.^[38]

Technology-Related Issues

Many of the problems that have been raised existed prior to the extensive use of information technologies, but these issues are magnified or aggravated through their applications in information environments. For example, circulation records collected in a centralized electronic storage computer provides additional vulnerability to invasions of privacy and confidentiality. Similarly, records of Internet searches may be saved electronically revealing the nature of information being sought and consulted by patrons. In addition, there are issues that have arisen because of the technologies themselves. The technologies are of two types: (1) intellectual technologies; and (2) computer technologies. Classification, cataloging, and indexing can be seen as intellectual technologies. As such, they provide a mechanism for providing access to the universe of available information; but at the same time, they may distort that universe, for example, classification schemes reflect the biases of the general population,^[39] and the very act of providing access to information, by applying a limited,

inaccurate, obsolete, or faulty set of descriptors to a particular citation, creates impediments to access.^[40]

There are also ethical issues associated with computer technologies that in part extend the intellectual technologies and that create their own sets of problems. One set of problems is related to electronic access. For example, incompetent searchers, ones insufficiently trained to deal with commands, syntax, and qualifiers of access and/or who is unfamiliar with the differences in databases, not only prevents access to the information for the patron, but also conceals their incompetence from themselves.^[41] Another set of problems concerns the library or information center–vendor relationships,^[42,43] including the use of consultants, fair bidding, licensing, and award practices.^[44]

Conflicting Loyalties

There are many varieties of ethical conflicts that emerge in the context of the information professions. There are conflicts between loyalties to oneself, one's organization, and the profession. For example, very often in information work information professionals demonstrate more loyalty to their organizations than to their professions,^[45] primarily because of economic motivations. This is unfortunate to the degree that such acquiescence to local authority may result in an endorsement of unjust pay scales or the inappropriate use of nonprofessionals. Martha Montague Smith provides a structure for articulating conflicting loyalties in a professional environment, and suggests that there are five possible levels of orientation in the workplace: (1) ideal ethics, which represents the highest aspirations or goals of an individual or group; (2) practical working ethics, which represents high aspirations, yet conformable to institutional, professional, and personal goals, is enduring but is also flexible and adaptable; (3) pressure ethics, which represents a scenario in which internal and/or external pressures split institutional or professional goals from those of workers; (4) subversive ethics, which represents a situation in which a small or large group of people advance what they perceive to be worthy goals for the profession or organization by working outside the system of articulated or tacit organizational goals; and (5) survival ethics, which represents a situation in which institutional demands threaten employee integrity, safety, or security to such an extent that individuals isolate themselves within the organization.^[46] These are various scenarios that information professionals may undertake, given a particular context of institutional life. What this framework underscores is that not only do ethical conflicts arise throughout the history of one's work in an organization, but that one's response to them may vary, depending on factors that affect organization life. While professionals should strive for the level of "practical working ethics," it is often the case that circumstances, such as declining budgets or forays at censorship of library

materials by patrons or groups, predispose professionals to operating at lower levels, such as "survival ethics." And of course, one may well be operating at different orientations with regard to different problems, one may undertake a stance of "practical working ethics" except for forays of censorship against the library, in which one's mode may be that of "subversive ethics."

Societal Issues

It is easy when discussing ethical issues of the information profession to forget that information agencies have a significant impact locally, nationally, and internationally. It is important to consider the ethical ramifications of this impact. Among the issues that foster ethical concern are the following:

1. To what extent does centralization over the control of information create a monopoly over the amount and quality of information being provided, and who receives the information?
2. To what extent do information technologies developed in Western societies, especially English-speaking societies, create a condition of cultural dominance over non-English speaking countries?
3. To what extent does information provided to lesser developed countries adversely affect the stability and health of those societies?

Such is a preliminary look at diverse ethical issues that arise in the information professions. The ALA has endorsed the importance of ethical conduct through the *ALA Code of Ethics*,^[47] a history of which is given in Lindsey and Prentice^[48] and through the ALA Committee on Professional Ethics. Similarly, the American Society for Information Science and Technology (ASIS&T) has issued the *ASIS&T Professional Guidelines*.^[49] But they are not without their problems (see, e.g., Barnes^[50]) so much so that they are frequently challenged for revision (see, e.g., Finks^[51]).

It is impossible in this brief entry to list all the resources available on ethical issues. For a fairly comprehensive bibliography, one can consolidate those provided by Hauptman et al.^[52] listed in the "General Introductions and Bibliographies" section of the Bibliography at the end of this entry. In addition to the articles cited here, resources are also provided in the sections: "Journals and Web Sites" and "Bibliography on Specific Topics."

FACTORS AFFECTING ETHICAL DELIBERATIONS IN THE INFORMATION PROFESSIONS

Libraries and other information organizations are subject to competing demands from a variety of sources, including the

public, clients, board members, administrators, and staff. Attempts to satisfy these demands often produce ethical tensions. Some authors have attempted to identify the ethical influences on librarians. McMenemy, Poulter, and Burton, for example, identified five influences: the employers ethical code; the professional association's ethical code, pressure from the customer to provide service, personal ethical beliefs, and society's ethical norms (p. 11).^[37] We would contend that when decisions are made, there are at least four factors that affect the deliberative process. These factors may not be consciously considered by the individuals making the decision, but are at least conceptually implicit and underlie the decision-making process. Such factors are not in and of themselves ethical principles; they are frequently considerations that come into play when ethical deliberations are attempted. Attempting to balance them often produces ethical frictions. It is therefore important to understand clearly the nature of these factors.

The Factor of Social Utility

All organizations have a purpose or a function. One might say, for example, that a public library's purpose is to meet the educational, cultural, informational, or recreational needs of its patrons or clients through the provision of materials and services. Insofar as the library performs such a socially valued service, it has a right to act in a way that would maintain and promote such activity.

Information organizations acting in this manner may make decisions that produce ethical qualms. For example, an organization may have to terminate an employee who is performing poorly because such performance interferes with the proper function of the organization. The employee may be a likeable individual whose performance may be the result of illness or personal problems, yet the decision to take action may be rationally based on the responsibility of the organization to execute its proper functions. Furthermore, the *Library Bill of Rights* of the ALA affirms the "Books and other library resources should be provided for the interest, information, and enlightenment of all people of the community the library serves" (p. 14).^[53] Such an assertion articulates a concern for the factor of social utility.

The Factor of Survival

One obvious purpose of organizations is to survive. This principle has been recognized in management theory for many years and is a simple recognition that organizations view their perpetuation as a central function. It is also grounded in philosophical traditions in which self-interest is recognized as a fundamental component of moral reasoning [^[54], Book III, Prop. 55; 55, Chap. XIV].

It is easy to envision an ethical issue in which survival is threatened. For example, if there is considerable public

outcry concerning certain "objectionable" materials in a library, the librarian may have to choose between removing library materials or facing a taxpayer's revolt. One is therefore tempted to censor library materials to ensure the physical survival of the library. This also highlights how the wish to preserve the library as a financially viable institution can come into conflict with a significant goal of the library—freedom of access to a diverse collection of materials. Ethical dissonance is bound to arise when one hopes to preserve the existence of the library by sacrificing in part its social utility (e.g., by reducing the number of hours a library is open so the library can continue to exist despite a constrained budget).

Factor of Social Responsibility

Another consideration involves the broader purpose that institutions—especially public ones—have. That is a purpose to serve the society at large and to promote the altruistic goals of that society. To this end, organizations might purchase and use recyclable materials whenever possible, promote "green libraries" that promote sustainable development in their own actions, in their patrons, or in the community,^[56,57] prohibit smoking on their premises, or employ only hiring and promotion policies that encourage equal employment opportunity and affirmative action. Of course, determining what "greater good" to satisfy is problematic, and would depend on the institutional values of the organization, the attitudes of those who direct an organization, and the political, economic, and environmental conditions in which the information organization is embedded. One may, for example, believe that the use of recyclable materials increases costs and hence negatively affects the survival and social utility of the organization. One may feel uneasy about affirmative action programs to the extent that they treat people as members of classes rather than as individuals. Nonetheless, when ethical deliberations are being made, organizations, especially those that provide a social service such as libraries, may take into account the need to accomplish and comport with broader social goals. This factor conforms to the second statement of the *Library Bill of Rights*: "Libraries should provide materials and information presenting all points of view on current and historical issues. Materials should not be proscribed or removed because of partisan or doctrinal disapproval." (p. 14).^[53] There is a tension between this statement and factor and the corresponding statement acknowledging the factor of social utility—one patron's meat is another patron's poison—but the library must provide a complete selection of coldcuts; that is, in providing information representing all points of view, the library may be acquiring material useful to one patron but offensive to others (e.g., *The Joy of Gay Sex*). The problem is that if some patrons obsess about "the poison," the survival of the library may also be at stake.

The Factor of Respect for Individuality

This factor recognizes that all individuals deserve to be treated with dignity and respect because they are people. It is a concept embedded in ethical traditions, most notably through the works of the eighteenth century German transcendental philosopher, Immanuel Kant, whose moral imperative required that we “Act in such a way that you treat humanity, whether in your own person or in the person of another, always at the same time as an end and never simply as a means.”^[58]

Respect for the individual has many implications for information functions. In terms of patrons or clients, it implies an obligation of the organization to collect materials and provide services that reflect diverse individual interests, wants, and needs, not just mass appeal. For public libraries in particular, this obligation has been noted by several writers as fundamental to the library’s collection-building function.^[59,60] This factor also implies that the organization provide service to people as individuals and not merely as members of a particular class, age group, race, sex, or ethnic background. In terms of employees, this factor implies that the library must treat its employees fairly, with respect and dignity. The organization must be responsive to individual employees’ feelings, wants, and needs. In addition, it implies that employees should treat each other in the same fashion and that administrators are also entitled to their *individual* opinions on issues, despite the position they may have to take in their managerial roles.

Such a factor may, however, generate ethical concerns. For example, in serving individual needs, should a public library sacrifice “mass appeal”? After all, appealing to the average consumer has the salutary effect of promoting taxpayer support (i.e., of increasing circulation), and reducing the likelihood of complaining patrons who are unhappy when materials representing unorthodox points of view are included in the collection. Ethical qualms might also be generated in terms of staff treatment; for example, when we fail to uniformly apply personnel policies by making exceptions for “individual circumstances.” We might be threatening the survival of the organization by subjecting it to potential legal liabilities and labor unrest. Finally, ethical qualms can be generated when we feel that we are not treating ourselves with respect. For example, we may be asked by others (employers, clients, competitors) to do something we believe is unethical. Acting in this manner diminishes us.

In attempting to make ethical judgments, these factors are constantly present. As ethical concerns arise, one might phrase concern for these factors in four questions:

1. To what extent is the survival of the organization threatened?
2. To what extent will the purpose of the organization be benefited or harmed?

3. To what extent is the organization or employee socially responsible or irresponsible when acting in a particular manner?
4. To what extent are the actions of the organization (or individuals acting in its behalf) harming or benefiting other individuals, organizations, or the profession?

The relative importance of these four factors depends on the specific situation and the seriousness of the effects. How should we make ethical judgments when so many competing factors are in operation? Before offering one possible answer it is necessary to examine a second ethical perspective, the professional dimension of ethical behavior.

PROFESSIONAL FACTORS IN ETHICAL DELIBERATIONS

The professional aspects of ethical behavior deal with the obligations and duties of information professionals while serving in the capacity of information providers. The Association for Library and Information Science Education (ALISE) has noted that ethical education “should be encouraged as an important aspect of education, research, scholarship, service, and practice in library and information studies and in other related profession.” ALISE encourages “special attention to information ethics. . .”^[61] As noted previously, most of our work decisions are made and actions taken with little or no ethical reflection. In this sense, we rely on our basic ethical training acquired in childhood and on our formal training regarding information work. This latter point is important, because it suggests that if our actions are often performed by habit rather than deliberation, then to the extent that information professionals are socialized into the ethics of the discipline, the greater the chance that these ethical standards become part of our basic ethical framework and will be consummated in day-to-day work life. It also places in relief the recognition that ethical training cannot be limited to “professionals.” Indeed, calling codes of conduct professional ethics diminishes their scope and underestimates the ethical responsibilities of all library workers. Nor should the concept of professional ethics imply that these ethics are different than those we use in everyday life, or that they should take precedence over those of everyday life. Professional ethics should be viewed as ordinary ethical standards applied in a particular environment.

The ALA has attempted through its code of ethics to provide ethical guidance, and it serves as a touchstone for the ethical socialization of librarians. This code states the following:

- (i) We provide the highest level of service to all library users through appropriate and usefully organized resources; equitable service policies; equitable access; and accurate, unbiased, and courteous responses to all requests.

- (ii) We uphold the principles of intellectual freedom and resist all efforts to censor library resources.
- (iii) We protect each library user's right to privacy and confidentiality with respect to information sought or received and resources consulted, borrowed, acquired, or transmitted.
- (iv) We respect intellectual property rights and advocate balance between the interests of information users and rights holders.
- (v) We treat coworkers and other colleagues with respect, fairness, and good faith, and advocate conditions of employment that safeguard the rights and welfare of all employees of our institutions.
- (vi) We do not advance private interests at the expense of library users, colleagues, or our employing institutions.
- (vii) We distinguish between our personal convictions and professional duties and do not allow our personal beliefs to interfere with fair representation of the aims of our institutions or the provision of access to their information resources.
- (viii) We strive for excellence in the profession by maintaining and enhancing our own knowledge and skills, by encouraging the professional development of coworkers, and by fostering the aspirations of potential members of the profession.^[47]

Adopted June 28, 1997, by the ALA Council; Amended January 22, 2008.

Published professional codes serve useful purposes. They provide support and guidance when ethical concerns arise and serve as a tool for the inculcation of values in library employees that are ideally assimilated into daily behavior. But articulation of such a code is frequently misleading; one must understand the values inherent in it. This points up the central defect of such a code. The "thinking" behind the code is obscure, because only a very few were present at the deliberations that created it or because the formalized, collective product reflects a compromise among divergent viewpoints. Understanding the thinking behind code is critical in understanding its meaning. But the thinking behind ethical codes is often dialectical and didactic, representing an articulation of perspectives, competing views, and the tensions among them. When one fails to recognize this evolution or rationale for codes, the codes are seen as finished and foster dogmatic beliefs. One merely invokes a provision of a code instead of offering cogent reasons that would justify the conduct prescribed by the code.

Ordinary ethical principles provide the framework for, and are not inconsistent with, the professional values of the information profession. Within that ordinary ethical framework, the information professional includes the values inherent in the information profession. Such values should personally guide the information professional when acting in this capacity. It is therefore ironic that the

ALA code specifically mandates that individuals separate their personal philosophy and attitude from those of their institutions or professional bodies (provision VII). What is actually desirable is that the individuals come to realize that there are important values of library and information service that should be a part of our own values when we serve in the capacity of information provider. This does not mean that individuals must give up other values to subscribe to those of the profession; rather, it is a recognition that the values of library and information service are worthy of admission to our individual value structure when we become information professionals. This sense of professional ethics becomes most important when individuals experience internal value conflicts while serving as information professionals, for example, when an individual who opposes abortion is asked to provide information on the topic. Although one may be personally opposed to abortion, one can also personally subscribe to the professional responsibility to be objective and to provide different points of view.

THE VALUES OF INFORMATION PROFESSIONS

It is fruitful to explore what values support the ethical principles of individual professional conduct. Understanding these values improves our ability to recognize ethical situations and to make ethical decisions and balance the competing organizational factors.

There are at least five values of the information professions that can serve as values of the individual as well as the organization (for a discussion of different values that are associated with the profession see Finks^[62]). These values can be characterized in the following manner.

The Value of Truth

Information professionals have as one of their important ends the advancement of truth and the search for knowledge. Certainly promoting truth fulfills a fundamental mission of the library (social utility) and meets a broader social end of improving the society as a whole (social responsibility).

The commitment to truth does not imply that information professionals, most notably library workers, should attempt to suppress materials they believe are untrue (or to promote materials they believe to be true, for that matter). To the contrary, as John Swan has aptly noted, untruths are essential to stimulate our thinking and reveal pathways in the search for truth (p. 49).^[60] The search for truth requires that the library provide an array of knowledge and information and access to expertise, so that individuals can apply their efforts in this search. Information professionals must act so that patrons and clients have the greatest opportunity to search for knowledge and truth.

This concept of truth as a value also pertains to the internal activities of the organization. Relations among

employees and administrators and between workers must have truthfulness as a value. Such actions as deception, withholding of information that is essential to the performance of others, and falsification of records abrogate this value. This does not mean that administrators or managers are ethically obligated to answer any question put to them. There may be occasions in which the appropriate response is to refuse to answer. Examples include answers that would violate confidentiality. Rather, the value of truth implies that when answers are given they are truthful. Information professionals must act so that employees treat each other truthfully in their actions and communications.

The Value of Tolerance

The value of tolerance is closely aligned with that of truth and its search. Many people seem to hold the belief that there is one truth, but libraries function on the assumption that many people believe many truths. A belief in the value of the pursuit of truth does not imply that “the Truth” is in fact achievable in all areas of life (science, ethics, religion, politics). One must tolerate diverse truths, and even if there were one truth, different people may use different avenues to attain it or to attain different aspects of it at a time.

It has been said many times in the writings of the library profession that the free exchange of ideas forms the basis of democracy and library services. A similar case can be made for most forms of information dissemination within and outside libraries. It is an ethical obligation of information professionals to promote exposure to different ideas, even those that are unorthodox. Decisions concerning library and information service that affect the free flow of such ideas ipso facto generate ethical concern. This does not require that information professional accept or be tolerant in all aspects of their life. One may, for example, not subscribe to the value of tolerance within the home. It requires only that one’s set of values reflects tolerance of ideas in the information workplace; that is, when one is performing library or information work, one must accept as a value that people have a right to information that one might find offensive. Parenthetically, the value of tolerance may not be as strongly held within the workplace. An employee, for example, whose remarks to other staff consistently cause demoralization and lower productivity might be disciplined or removed. But from the perspective of information service, it is essential that library professionals act so that library and information services increase the flow of ideas.

The Value of Individual Liberty

Library and information service is meant to assist individuals in their individual pursuit to have a better life. This does not mean that each time an information worker answers a question it profoundly alters a patron’s life, but

it does imply that every time questions are answered correctly the patron is able to accomplish a task, resolve a problem, or plan their future just a little better. In this way, the profession assumes that not only individuals, but organizations and society as a whole are changed, and, in the long run, improved by ideas. Improvement may mean many different things: providing information to a scientist to discover a new drug; stimulating the imagination of a child by providing reading or viewing material; providing training information to adults; or providing programming for mothers or the elderly. Actions that would impair this important function interfere with the basic liberties of people to make their lives better and generate ethical friction. Information professionals should therefore act so that library and information services respond to the information wants and needs of users.

The Value of Justice

This value pertains both to information users and to fellow information professionals within a given organization. From the public perspective, it implies that all citizens have equal access to library services. But even in nonpublic settings, it implies that all individuals should receive the best quality service. Similarly, for both private and public information organizations, it implies that the delivery of inferior information service on the basis of race, sex, religion, origin, disability, sexual orientation, or age is a violation of such a value.

But the concept of justice is complex, and a distinction noted by the philosopher John Rawls is especially appropriate in the information context. Rawls realized that justice cannot be understood merely as equality, but as “fairness” (p. 168–169).^[63] One may, for example, accept as just the fact that the library director and maintenance worker are paid unequally. This is an important distinction because it implies that ethical action requires fair rather than equal service or treatment. Unequal service might, in fact, be an ethical obligation if the needs of individuals differ. This recognizes, for example, that children may receive unequal service because their needs are different from those of adults, or that less knowledgeable adults may require different levels of service. The value of justice implies that we do not necessarily provide equal service, but that we provide service that recognizes individual circumstances. This does not imply that equality is absent in the concept of justice or library ethics. Equality of *access* to information services is certainly inherent in the concept of public library and information service, and fairness in access is inherent in any information service. The information professional must act so that library services are provided fairly to all users.

The value of justice also applies to the internal workings of library and information services. Employees should be treated fairly and consistently by managers and administrators, and equal access to opportunities within

information organizations must be provided. In addition, this value implies that employees should treat each other fairly. To this end, the library professional must act so that employees are treated and treat each other fairly.

The Value of Beauty

The value of beauty suggests that librarians have a deep and abiding respect for those works that please and educate. This includes works that occupy a notable position in literature and the arts. Such works are valued because they broaden and deepen human understanding. It also includes works that provide pleasure and recreation to all individuals. Such a value implies that librarians make such collections available. Similarly, it is common that such collections come under attack by censors who feel that even classics (e.g., *Huckleberry Finn*), should be restricted or removed. Librarians must act so that works that provide aesthetic experiences be maintained, preserved, and available to users. Such a consideration may also imply an obligation that materials of high literary quality not be sacrificed with excessive attention to mass appeal (e.g., excessive quantities of gothic romances).

ACTIONS THAT PROMOTE ETHICAL CONDUCT

If one assumes that these values play an important role in ethical actions for information professionals, then it is important to determine what actions information organizations and librarians can take to promote ethical actions. These actions can be seen from three perspectives: organizational, individual, and professional.

Organizational Actions

When attempting to balance the factors that generate ethical tensions in organizations, the values of library and information service are pivotal concerns. For example, when library staff, supervisors, administrators, or board members make decisions or take actions that could affect the organization's utility or survival, one must also reflect on the central values that make the library what it is. To the extent that one sacrifices these values to other ends, one must accept the diminution of ethical standards. Few complex decisions in the workplace produce wholly satisfactory resolutions, even when the decision maker believes that no better decision could be reached. There is often a residue of uneasiness, sometimes because one suspects that an ethical dimension has been abandoned for the sake of utility or self-interest. It is every information professional's responsibility to maintain an ethical environment, but this is also a special responsibility of the management because of the increased ethical burden. Below are a variety of actions that the leadership of information organizations might take to meet this burden:

1. *Have a board and administration committed to leading by example.* Each individual is responsible for his or her own ethical actions. But these actions are also, in part, modeled by the behavior of those in authority. Rules and regulations are important and influence employee actions, but the ethical environment is a culture that is shaped as much or more by example than by rule. For this reason, the actions of board members, administrators, and supervisors must be ethically exemplary.
2. *Establish a written ethics policy.* The library's commitment to ethical behavior should be formally stated along with the rationale for that behavior. A professional code may be part of this commitment, but it is not in and of itself sufficient. The policy should include a clear statement on the part of the board and administration regarding their commitment to ethical conduct in relation to the patrons, the profession, and the organization. For example, it should be an ethical responsibility of staff
 - a. To promote a sense of confidence about the organization and its purpose with the public or appropriate clientele.
 - b. To make the organization as effective and efficient as possible both internally and with its relations with the public or clientele.
 - c. To strive for personal and professional growth.
 Such a written policy should also include what will happen to employees who violate these ethical obligations, and how such violations can be reported. Although it is hoped that employees, once they understand the rationale for ethical behavior, will comport with that behavior, the organization should have some means to sanction those who violate ethical conduct. Otherwise, some employees may interpret the organization's position as "lip service." However, unusually severe punishments, especially for first infractions, are undesirable, because it would tend to inhibit reporting of such infractions if observed by others (p. 76).^[57] Penalties for ethical violations should be progressive, with early violations being dealt with through discussion. Whenever violations occur, action should be taken swiftly, and continued violations should be dealt with harshly.
3. *Conduct orientations that include discussions of ethics.* When new employees are hired, it is important not only to provide them with general information concerning the mechanics of the organization, but also to begin the process of socialization, inculcating the values of public service. In such a discussion, the new employee should receive a clear understanding of what constitutes ethical and unethical conduct. Emphasis should be placed on the important role that the organization plays and the organization's commitment to the values noted above.

4. *Conduct staff development and training programs.* It is not enough to mention ethical concerns at the time of hire. Employees must experience ongoing reinforcement. This will increase the chance that ethical actions will become habitual. Emphasis should not be placed on the rules themselves, but on the values and deliberations that underlie such rules. It should be assumed that individuals want to behave ethically, especially when they understand how important such conduct is, and how destructive unethical conduct can be in terms of loss of trust and confidence of the public or of other staff. Programs and meetings on ethical issues should therefore be a regular part of staff development and training for all staff and might include case studies in which staff actually go through ethical deliberations that reveal the conflicting tensions within information organizations.
5. *Hire and promote individuals with ethical awareness.* There are many aspects that must be considered when hiring and promoting individuals. One area to explore is how they deal with job-related ethical issues. It should be kept in mind that organizational environments are very powerful. A newly hired employee may possess considerable scruples, but if the prevailing ethics of the organization tolerates unethical conduct, then new hires, in order to fit in, may well adapt rather than attempt to change the environment.

Professional Actions

Ethical conduct should also be promoted by the information profession itself to ensure that the standards of conduct are consistent with the highest levels of professional service.

1. *Create a code of conduct.* A professional association can be seen as the voice of a profession. The most obvious channel used by a profession is to establish a written code of ethics and create sanctions for those who violate it. These sanctions, found in such professions as law and medicine, include temporary or permanent suspension of a professional's ability to practice. Codes, however, may not have sanctions and it may be undesirable for all professions to have them. The ALA has no sanctions for its code of ethics, nor does ASIS&T for its professional guidelines, and hence, comportment with these codes is strictly voluntary. Although sanctions can promote certain types of behavior, they may do so for the wrong reason—fear of punishment. The purpose of an ethical code is first and foremost to promote ethical understanding. Focusing on penalties diverts attention from understanding the values that should determine our conduct.
2. *Offer training and advice in ethical conduct.* Professional associations are also obligated to reinforce their

codes of conduct by providing programming and information on ethical issues. Associations such as the ALA and ASIS&T provide such programs, usually at their conference sites. In addition, the ALA has divisions that deal with ethical concerns, including the Committee on Ethics, which considers ethical issues and infrequently provides materials that promote discussion of ethical concerns (e.g., the *Ethics Sin List*^[65] and the Intellectual Freedom Committee which deals with ethical issues when they coincide with intellectual freedom issues). It is notable, however, that the Committee on Ethics does not operate like the Intellectual Freedom Committee in that it does not promulgate official interpretations of the code of ethics or intervene in ethical matters outside the association. Similarly, the Professional Committee of ASIS&T issued the ASIS&T Professional Guidelines, but does not promulgate its interpretations or intervene in ethical matters outside the association.

Individual Actions

Ethical actions are associated most often with the conduct of individuals, and there is a clear obligation for information professionals to act ethically in regard to the provision of library and information services.

Information professionals are obligated to act ethically on at least three different levels: they have a responsibility to their profession, to their employer—clients—system users, and to the society as a whole. The ASIS&T Professional Guidelines has set forth the following provisions (abridged):

1. *Responsibilities to employers/clients/system users*
To act faithfully for their employers or clients in professional matters;
To uphold each user's, provider's, or employer's right to privacy and confidentiality and to respect whatever proprietary rights belong to them by limiting access to, providing proper security for and ensuring proper disposal of data about clients, patrons, or users;
To treat all persons fairly.
2. *Responsibility to the profession*
To truthfully represent themselves and the information systems which they utilize or which they represent. . .
3. *Responsibility to society*
To improve the information systems which they work or which they represent to the best of their means and abilities. . .
To promote open and equal access to information, within the scope permitted by their organization, and to resist procedures that promote unlawful

discriminatory practices in access to and provision of information. . . .^[49], adopted May 30, 1992].

These principles can easily be applied to librarians as well as information scientists and other kinds of information professionals.

ETHICAL DILEMMAS

Even with these responsibilities clearly delineated, there are times when the values of information provision appear to conflict with other personal or social or cultural values. This conflict is most conspicuous when the values of information professionals appear to conflict with commonly accepted notions of moral or right conduct. A common example, involving a public library, highlights this type of situation:

An adolescent child comes to the librarian in a public library and asks for a book on how to commit suicide. The child looks very depressed and upset. The librarian is aware of a book that would provide substantial amount of accurate and up-to-date information on committing suicide. The librarian is also aware that the material would really be understandable to the patron. What should the librarian do?

Admittedly, this situation is contrived and its occurrence would be very rare. Nonetheless, it places into relief a situation in which the information provider's general concept of right conduct (the belief that one should not intentionally harm another person) seems to conflict with one's obligation to respect individuals and their right to information. Of course, implicit in this situation is the belief that the individual will in fact commit suicide. If this was actually known, then providing the information could hardly be defended by invoking provisions of the ALA code of ethics or any other professional code. Nor could one sensibly say that one is obligated to find this information for the patron because of a person's "right to information." Such a rationalization is contrary to our everyday ethical notions of right conduct.

But the situation described above is extraordinary and presupposes knowledge seldom, if ever, available to the information professional. In almost every case, the knowledge of the librarian regarding the patron is imperfect and very limited. This is due to the fact that most patron contacts are very brief. Librarians seldom have substantial information about the personal lives of their patrons or their psychological condition, nor are they qualified to evaluate this information. Consequently, the librarian has little or no ability to predict what a patron will do with the information and the consequences of the patron's actions. In the vast portion of circumstances, acting consistently with the values of the information profession does not require that one give up one's ordinary concept of moral

action; rather it is to accept the ethical obligation to recognize the individual's right to information. Such an obligation could only be violated with clear knowledge that significant harm to others will result. It is also to recognize that the information provider's predictive ability regarding the consequences of the information provided is minimal at best. The duty of the librarian is to accept the right of individuals to receive information and to use that information. Although librarians may be concerned as to how certain information may be used, without sure knowledge of such misuse and the substantial harmful consequences of the use, it becomes too easy for the information professional to project those consequences inaccurately, with harmful ethical consequences of their own.

The dilemma posed by the suicide example brings out another point about the purpose of information giving. One can view information provision simply as an obligation to answer a specific question, but this is an inappropriate and impoverished model for the information professional. The purpose of information giving should be seen in the broader context of resolving an information need of problem. This is consistent with the notion that the purpose of information giving is to assist the patrons in living their lives in the manner they see fit. It is the "problem context" or "problem environment" of the patron^[66] that is the focus of the information provider. In this context, information providers need to know the context in which information is requested. If, in the unlikely ethical situation posed, a librarian actually had a strong suspicion that a patron was going to use the information to commit suicide, the information provider would in fact be obligated to locate additional information (perhaps the name and telephone numbers of suicide counseling agencies or community mental health agencies) that might resolve the problem in a manner that would promote the health of the individual. In other words, the information question involved how to commit suicide, the information problem was actually unstated: "How can I deal with a life so difficult that I wish to end it?"

There is no simple way to resolve the myriad of ethical problems that confront information professionals, but the fact that ethical issues are complex does not relieve us of the burden to act ethically.^[67] On the contrary, the absence of ethical concerns would make the information profession very dangerous. As the information professions mature, expand, and grow in importance, information professionals need to redouble their efforts to define their ethical responsibilities and find the means to ensure that all professionals are aware of and accept their ethical obligations.

Ethical Issues in Information Systems

Vladimir Zwass

*Computer Science and Management Information Systems, Fairleigh Dickinson University,
Teaneck, New Jersey, USA*

Abstract

Information technology and information systems built around its artifacts can have powerful effects on individuals, both in their private life and in the workplace. As professionals and users, we should use ethical principles and codes of ethics to avoid and prevent deleterious effects of technology. Infoethics is the application of ethical theories to the development and use of information systems. The principal infoethical issues are privacy, accuracy, property (in particular, intellectual property), and access. These issues have come into a sharp focus as we spend ever more of our time online and as our actions are mediated by systems available over the Internet. Ethical decisions in the information-related domains are made by identifying the issues involved and applying ethical theories—classified as consequentialist and deontological—in the decision-making process.

INTRODUCTION

Information technology (IT) offers potent tools that can serve to fulfill an individual's life, to further organizational goals, pursue national and international interest, or support environmentally sustainable regional development. The same technology can also be used to infringe on property in a digital form, invade individuals' private sphere, and to hold them in fear of omnipresent surveillance. The way the technology is deployed depends on our decisions as professionals and as users of information systems. It also depends on the policies enacted by the government and business organizations, and on legislation. All of us, therefore, should make the relevant decisions guided not only by the economic, organizational, and technological aspects of information systems, but also in consideration of their effects on individuals. Our knowledge of ethics helps us in making such decisions. Furthermore, this knowledge can inform the evolution of the relevant public and organizational policies. What we may call infoethics is the application of ethical thinking to the development and use of information systems.

Ethics and Codes of Ethics

Ethics is a study of the principles of right and wrong that ought to guide human conduct. Ethics concerns itself with what values are worth pursuing in life and what acts are right. Therefore, ethics is a study of morality.

Human behavior and decision-making fall into three domains, as shown in Fig. 1. The legal domain governs a variety of relatively well-defined behaviors, specified by law enforceable in the courts of a given country or within a local jurisdiction. International bodies increasingly address legal issues that cross national borders. Computer crime and abuse, such as the destructive deployment of

malware (e.g., computer viruses or worms) or misrepresentation of electronic identity toward financial gain, are the breaches of law and fall into this domain.

However, not every legal action is ethical. The domain of ethics is governed by the general norms of behavior and by specific codes of ethics. To see whether your decision-making in a given case involves an ethical issue, you may apply the "sunshine test": "What if I read about my decisions and subsequent actions in tomorrow's paper?" Ethical considerations go beyond legal liability, and the breach of norms not punishable by law meets with social opprobrium. Only if the action is both legal and ethical, does it fall in the discretionary domain, where we properly act entirely according to our preferences.

Knowledge of ethics as it applies to the issues arising from the development and use of information systems, which we may call infoethics, helps us to make decisions in our professional life. Professional knowledge is generally assumed to confer a special responsibility in its domain. This is why the professions have evolved codes of ethics, that is, sets of principles intended to guide the conduct of the members of the profession. The principal code of ethics for information systems professionals is the Association for Computing Machinery (ACM) Code of Ethics and Professional Conduct, binding on the members of the ACM.^[2] The code should be familiar also to all whose professional life is affected by information systems. We have reproduced the fundamental statements of the ACM Code in Fig. 2. In addition, corporations and other employers should establish their own codes of infoethics. Such corporate codes have been shown to influence the behavior of people who would otherwise not think that an important ethical issue was involved in their decision-making.^[3,4]

To select a course of action in an ethical dilemma, we turn to ethical theories.

Fig. 1 Domains of pursuit in problem-solving or opportunity-seeking with information systems.

Ethical Theories

Ethical theories give us the foundation for ethical decision-making. Some of them are grounded in an individual's pursuit of virtue, such as justice or generosity. While important in the development of the moral sense of individuals, these lend themselves, only to a limited degree, to a reasoned decision-making process. There are two fundamental effective approaches to ethical reasoning:

- Consequentialist theories tell us to choose the action with the best possible consequences. Thus, the utilitarian theory that prominently represents this approach holds that our chosen action should produce the greatest overall good for the greatest number of people affected by our decision. The difficulties lie in predicting the consequences of an action, and in deciding what the "good" is and how to measure and compare the resulting "goods." The approach may also lead to sacrificing the rights of a minority. A social contract

among the members of social groups implies the need to consider the lot of all these members. There are certain acts that are wrong in themselves and should be always avoided. These unethical acts interfere with the rights of others, the rights that may be derived from the other principal group of ethical theories.

- Deontological theories argue that it is our duty to do what is right. Your actions should be such that they could serve as a model of behavior for others—and, in particular, you should act as you would want others to act toward you. Our fundamental duty is to treat others with respect—and thus not to treat them *solely* as a means to our own purposes. These theories have been assailed by the claims that varieties of cultures exist, with differing norms and models of behavior.

Treating others with respect means not violating their rights. It is, therefore, vital that we recognize the rights of each human individual. The principal individual rights, enshrined

1. Contribute to society and human well-being.
2. Avoid harm to others.
3. Be honest and trustworthy.
4. Be fair and take action not to discriminate.
5. Honor property rights including copyrights and patents.
6. Give proper credit for intellectual property.
7. Respect privacy of others.
8. Honor confidentiality.

Fig. 2 General moral imperatives of the ACM Code of Ethics and Professional Conduct.

Source: From ACM Code of Ethics and Professional Conduct.^[2]

in the United Nations' Universal Declaration of Human Rights and recognized in liberal democratic societies, are

1. The right to life and safety
2. The right of free consent—individuals should be treated as they freely consent to be treated
3. The right to private property
4. The right to privacy
5. The right of free speech, extending to the right to criticize truthfully the ethics or legality of the actions of others
6. The right to fair treatment—individuals who are similar in regard relevant to a given decision should be treated similarly
7. The right to due process—individuals have a right to an impartial hearing when they believe their rights are being violated.

Recent work by ethicists attempts to make ethical theories more effective in practice. An ethical theory that supports a process of deliberation between the future system users and its developers is discourse ethics, grounded in the theory of communicative action of Jürgen Habermas.^[5] The emerging empirical moral psychology attempts to relate the actual human behavior in ethically challenging situations to the precepts of ethical theories.^[6] Thus, we learn empirically about the implicit or explicit use of ethical theories by information-systems professionals in their decision-making processes.^[7] This helps us inculcate values and ethical decision-making modes. The application of ethical theories is best illustrated by considering practical cases, which we will now proceed to do.

SCENARIOS IN THE ETHICAL DOMAIN

Consider the following three scenarios, adapted from Parker.^[8] We will come back to these scenarios after we discuss the tenets of infoethics.

Transactional Information on Smart Cards

The manager of the smart-card division of a financial institution has developed a new debit card as a smart card, containing a microprocessor chip with memory. Unbeknownst to its holder, not only the amount spent was debited, but also detailed data about every purchase transaction were stored on the card. As a result, any merchant presented with the card could evaluate the credit history of the cardholder. The financial institution was also planning to allow the merchants to upload the data from the smart cards to their own servers. This would enable the retailers to use personal information about their customers for promotional purposes.

Consider these questions: Do you believe that there are any ethical issues involved? If so, what ethical principles were breached?

Who Owns E-mail?

A firm had a policy allowing employees, upon approval, to use their personal devices, such as PCs, laptops, tablets, and smartphones, which were the property of the company, for personal purposes, including e-mail and web access. When a possible acquisition of the company by another one was announced, a rising employee unrest was suspected. The president of the company ordered the security department to use specialized software to monitor all the online activities of the employees, including the contents of their memos, e-mail messages, budgets in preparation, and so forth. Reports produced by the security department detailed what the employees produced both during their work and during private use of their devices. The monitoring and reporting was done without employees' knowledge.

Was the action of the company management ethical or unethical in allowing personal use of corporate IT by employees? How about the president's monitoring decision?

Let's Just Release This System

A project leader in the corporate information systems division was assigned by her manager, the vice president of sales for the company, a task to develop a new Internet-based billing system. When the work was being assigned, the project leader thought that the time and human resources provided were adequate to complete the project. However, due to an unexpected turnover of computing specialists, it became clear that the system could not be completed as designed within the available budget and time frame. The project leader warned her superior about the impending problem. She was forced to deliver a "bare bones" system, without adequate error detection, exception handling, security safeguards, and audit trail. When the system was fielded, it became a source of problems in customer service. Many customers were billed incorrectly and, following heated exchanges, switched suppliers. Cases of fraud were discovered but proved impossible to trace. Business losses resulted and the project leader was blamed.

Was the action of the project leader ethical in knowingly implementing an inadequate system? How would you evaluate the actions of her superior in ordering an inadequate system into production?

The following general discussion of infoethics will allow us to discuss the issues involved in these cases.

ETHICAL ISSUES IN THE DEVELOPMENT AND USE OF INFORMATION SYSTEMS

The welfare of individuals and their specific rights, postulated by the ethical theories we discussed, need to be safeguarded in the environment of an information society. The principal ethical issues of concern with regard to information systems may be categorized as privacy, accuracy, property, and access.^[9]

Fig. 3 Ethical issues, their sources, and the underlying individual rights.
Source: From Zwass.^[1]

We have shown these principal ethical issues as the four circles in Fig. 3. As shown in the figure, we can trace these issues to their sources: 1) the pervasive role and immense capabilities of systems for collecting, aggregating, storing, communicating, and accessing information in our information society; 2) the complexity of IT; and 3) the intangible nature of information and digital goods, such as digitized music or software. We also show in the figure the specific individual rights whose potential violation brings the issues to a head.

Tracing an ethical issue to its source and understanding the individual rights that could be violated help us understand the issue itself. For example, the intellectual property (IP) rights embodied in digital goods, such as software, are relatively easily violated because software is intangible and can be easily copied at a marginal cost close to zero. At the same time, the development costs of software are very high. Since IT pervades so many aspects of our lives, particularly after the infusion of the Internet–web compound, our privacy can be more easily violated than in the absence of this technology. Indeed, without computerized databases accessible over the Internet, fed by information systems that process our purchases, loan applications, insurance policies, and other transactions, it would hardly be possible to assemble the detailed record of our lives within fractions of seconds. With the broad move to business analytics based on the many trillions of facts collected about individuals as “big data,” our lives can be laid bare through the use of IT. Access to the information-based systems enhances our lives and the commercial activity in uncountable ways, as it exposes us to privacy risks. At the same time, those bereft of access to the technology are impaired in many of the life’s pursuits and their right to fair treatment is violated. An individual in a modern society who cannot make use of the Internet is deprived of a principal source of information,

transactions, and relationships, and the means of self-expression. A handicapped person without effective access to IT in a society where such use is needed to work is not treated fairly. We will now proceed to consider the four ethical issues in the following sections.

PRIVACY

Privacy is often considered the most important ethical issue raised by information systems. Privacy is the right of individuals to retain certain information about themselves without disclosure and to have control over the information collected about them. When our privacy is invaded, we are embarrassed, diminished, and perceive a loss of autonomy—a loss of control over our lives. Invasion of privacy is a potent threat in an information society. Individuals can be deprived of opportunities to form desired professional and personal relationships or can be politically neutralized through surveillance and gathering of data from the myriad databases that provide information about them. Most authorities agree that it is necessary to uphold the right to privacy as a basic individual right; Justice Louis Brandeis, over a century ago, called this right “the most valued by the civilized man.” Even though this right is not guaranteed by the Bill of Rights in the United States, that constitutional document stresses that other rights, beyond those enumerated there, are retained by the people. The right to privacy is considered to be such a right.

Concern about privacy had existed for many years before computer-based IT entered human affairs. Yet, computer-related technologies, and especially the massive use of the Internet–web compound, create opportunities for privacy invasion that had not existed previously. As much of our lives are now lived online, traces are left of

our behaviors and activities which may persist for decades. Databases containing minute details of our lives can be assembled at low cost, fused with others, and made accessible anywhere and at any time. A web search can be conducted at the behest of a governmental or business institution, or in a personal pursuit, to be augmented by information acquired from a data broker, that will yield a comprehensive profile of an individual.

Collection, storage, and dissemination of records concerning individuals are all necessary to our business, government, indeed, to the very fabric of our lives. To balance this need with privacy protection, both legislation and ethical approach to the acquisition and use of these records are necessary. In the United States, privacy is protected by a variety of legislative acts, the most prominent of which is the amended Privacy Act originally enacted in 1974, which regulates the treatment of personal data by federal agencies. The handling of personal information by corporations has received far less legislative attention, and the essential legal mechanism in this case is the law of contract. A 1999 U.S. law requires financial institutions to send out their privacy policies to their customers. The Health Insurance Portability and Accountability Act (HIPAA) provides privacy protection for medical records. However, gaps in legislation and in its enforcement make it difficult to protect privacy through the legal system and leave much of the privacy issue in the domain of ethics.

The Privacy Act and the legislation that follows it specify the limitations on the data records that can be kept about individuals and are based on what is known as Fair Information Practice Principles. These principles also underlie the guidelines set by the Organization for Economic Cooperation and Development (OECD). These fundamental privacy safeguards are the following:

- Individuals should be given notice of the information practices of the entity that wishes to collect personal information from them.
- No use can be made of the records for other than the original purposes without the individuals' consent.
- Individuals have the right of inspection and correction of records about them.
- The collecting agency is responsible for the integrity and security of the record-keeping system.
- There is a mechanism in place to enforce the safeguards and offer redress.

These principles lie at the foundation of the Consumer Privacy Bill of Rights fostered by the United States executive branch as the framework aiming at limiting the scope and increasing the transparency of data collection practices by business organizations.^[10] Ensuring privacy in the face of rapidly expanding technological possibilities for its invasion is not easy. Controversies arise and the trade-offs involved test the ethical frameworks. Many privacy advocates favor an opt-in practice in soliciting personal information. In this case, the individual releasing the

information needs to consent expressly to the information being used for the purpose specified by the requester. An alternative, the opt-out regime, favored by information collectors, makes the release of the information a default in the absence of an express prohibition by the individual.

Legislation and enforcement in the area of privacy in the United States are behind those in a number of other countries. Much is left to spotty self-regulation by business entities. Privacy statements to all clients by financial companies in the United States typically include such tropes: "We also may share information with other companies that are able to extend special offers we feel might be of value to you." Opt-out options are cumbersome. Online privacy policies have been found to aim at protecting the firms from litigation rather than reflect a commitment to fair data practices.^[11]

The countries of the European Union (EU) offer particularly extensive legal safeguards of privacy. In the environment of business globalization, this creates difficulties in transborder data flow, that is, transfer of data across national borders. Countries with more stringent measures for privacy protection object to a transfer of personal data into the states where this protection is more lax. Therefore, a number of U. S. corporations have signed the so-called safe harbor agreement, complying with the EU privacy standards. The United Nations has stated the minimum privacy guarantees to be incorporated into national legislation. The harmonization of privacy regimes across borders remains a challenge.

Privacy safeguards, such as privacy policies posted on websites, even when audited by independent agencies (e.g., TRUSTe, <http://truste.org>), are insufficient to protect this information from abuse. A common loophole is the dissolution of the original firm that had collected the information under certain safeguards, for example, during a merger or an acquisition. Conflicts arise between an individual's right to privacy and the right of a larger community to protect itself.^[12] Such issues include the rights of governments to decipher encrypted messages in the cases of suspected terrorism or crime, or the rights of parents to have access to the records of sex offenders who may endanger their children's welfare. In discharging their responsibility to enhance national security, governments may move to take away the ability of individuals to remain anonymous in a variety of situations, for example, by demanding identification in the airports.

The marketing and personalization of products and services acquired and sometimes also delivered over the web requires personal information about the consumer. Recommender systems that facilitate our online transactions rely on the minute knowledge of our buying habits. Effective m-commerce, that is, relationships and transactions conducted over smartphones and other mobile devices, indeed calls for consumer intimacy: The more information the system stores about the user, the higher is the speed and quality of the interaction.^[13] Pervasive information systems that introduce ubiquitous computing and sensing technology into everyday objects magnify the exposure to

potential intrusions on privacy.^[14] Fair Information Practice Principles should serve as the essential decision-making guideline. Matching of the online profile with personally identifiable data is of particular concern. Privacy concerns should inform technological solutions in system fielding; such concerns are, for example, debated before the radio-frequency identification tags are deployed on a wider scale.^[15] There are various methods of de-identification in data sets, which should be considered before releasing the data from the originating organization.^[16]

Information systems have made it possible to conduct systematic monitoring and surveillance of persons and groups. Among the technologies are the video-based systems that monitor city traffic for infractions, as well as the systems that monitor the use of rental cars to account for driving habits. The use of cookies and monitoring of the clickstream by websites, while facilitating commercial transactions and marketing, is troubling to many. Device fingerprinting allows monitoring users' online behavior even in the absence of cookies.^[17] Tracking an individual's whereabouts with a geographic positioning system, embedded in a cell phone, although useful in m-commerce, presents a danger to privacy. Notably, human mobility traces are unique and can easily lead to identification.^[18] Focused and context-specific data collection is a basis for privacy.

Aggregation and analysis of "big data" enables a broad product and process innovation, with evidence-based decision-making in various sectors of the economy. Of special concern is the personally identifiable information (PII), that is, the information that can be traced to an identifiable individual. The powerful and economically important use of the "big data" also creates new privacy risks with the commodification of data, including in many cases PII, and the loss of control over their flow and aggregation.^[19,20] Since the value of the "big data" emerges mostly in its multiple and varied secondary uses, great care has to be exercised over the aggregation.^[21] There are many options available to IT designers to build systems that foster limitations on the collection and transmission of PII with, among other measures, "privacy patterns" to be used in building the relevant software.^[22]

Two database phenomena create specific threats of privacy invasion. The first, database fusion, makes it possible to merge separate facts collected about an individual in multiple databases in order to develop a comprehensive profile of a person. If minute facts about an individual are put together in this fashion in a context unrelated to the purpose of the data collection and without the individual's consent or ability to rectify inaccuracies, serious damage to the person's rights may result. The dispersion of personal data among several independent databases is one safeguard against invasion of privacy. The other concern relates to statistical databases that contain large numbers of personal records, but are intended to supply only statistical information (the U.S. census database is the best example). A snooper, however, may deduce personal information by constructing and asking a series of statistical queries that would gradually narrow the

field down to a specific individual. To prevent such disclosure, limitations on the allowed queries need to be placed (e.g., a query would not be answered if the answer would refer to fewer than 10 persons).

Active generation of online content by users leads to exposures we are just learning to control. Cocreation of value by users and consumers, along with the producers, through user-generated content and through conducting their relationships online has become a major economic factor.^[23] Users are offered access at no charge to a great variety of social networks and expression media – and the content they produce and the traces they leave become the property of the sites. For example, these sites have become media for the management, or even manipulation, of one's public persona. Such reputation management often surrenders various aspects of the individual's privacy, to the individual's future regret. Social norms in that respect are in a state of flux.^[24]

As privacy norms are being formed and as laws are emerging, it is important to consider the context of the system use and the expectations of privacy in that context, be it private life, school, or workplace.^[25] The complexity of this consideration comes from the pervasiveness of IT throughout the various—and interlocking—contexts of our lives. Although we cannot "engineer privacy," there are numerous practices that can serve the goal of controlled approach to data.^[26] As stated in Fig. 2, the ACM Code of Ethics obligates information systems professionals to "respect the privacy of others" and goes further to offer specific guidelines on how to do that.

ACCURACY

Pervasive use of information in our societal affairs means that we have become more vulnerable to misinformation. Accurate information is error-free, complete, and relevant to the decisions that are to be based on it. Accurate information is grounded in high-quality, secure information systems, constructed by responsible professionals. OECD data quality principle states that the data "should be accurate, complete, and kept up-to-date."^[10] Although stories about inaccurate information surface most frequently with regard to the credit-reporting industry, they reflect a generally low level of data quality control throughout the public and private sectors of the economies.

Inaccurate information can prevent an applicant from obtaining a credit card—or a job. When people rely on inaccurate information, other people may be deprived of their right to due process. An incorrect medical record can threaten your life. A weather report that incorrectly forecast the trajectory of a storm because the data from a failed buoy were unavailable to the computerized model sent a sailor to his death.^[9] French police officers, in hot pursuit of a car recorded as stolen in their database, opened fire and wounded a law-abiding driver. The records of the car recovery by the legitimate owner and of the subsequent sale of the car were missing from the database. Multiple

accidents involving massive radiation overdose administered by the radiation-therapy system Therac-25 have been traced to imperfectly tested software.^[27]

Is the development of information systems that provide accurate information just the question of professional competence? In the third scenario presented in “Scenarios in the Ethical Domain,” a “bare-bones” system was knowingly forced through by a firm’s executive and knowingly implemented by a project leader. Similar events could have been behind any of the systems that led to the loss of individual welfare—or life—in the cases we just described. Beyond that, there exist various sources of possible bias in information systems—and the information system developers should be aware of that. The bias of concern to infoethics represents a persistent discrimination against certain categories of individuals and groups reflected in the design of an information system, which negatively affects the accuracy of information provided.^[28] Data analysis grounded in the “big data” may extrapolate individuals’ behavior from that of “people like them” and, possibly, punish an individual for the expected, rather than the actual, deeds.^[21] Professional integrity is an essential guarantor of information accuracy.

An ethical approach to information accuracy calls for the following:

- A professional should not misrepresent his or her qualifications to perform a task.
- A professional should indicate to his or her employer the consequences to be expected if his or her judgment is overruled. The ACM Code of Ethics and Professional Conduct speaks of the professional’s obligation to “avoid harm to others” by carefully assessing potential impacts of an information system to be implemented.
- System safeguards, such as the controls and audits, are necessary to maintain information accuracy. Regular audits of data quality should be performed and acted upon.
- Individuals should be given an opportunity to correct inaccurate information held about them in databases. The sources of inaccuracies should be tracked down and eradicated.
- Contents of databases containing data about individuals should be reviewed at frequent intervals, with obsolete data discarded.

Regrettably, some information-systems professionals are likely to choose implementing a system with quality problems in the conditions known as moral hazard, that is when they have an incentive to act in their own interests and against the interests of their employer, while being able to hide this.^[29] The same research has also shown that the ethical climate of an organization can influence these actions in the positive direction.

Accuracy problems have wider societal implications. A claim has been made that the absence of proper controls

in some computerized election systems may threaten basic constitutional rights. An independent assessment of the e-voting systems certified for use in the State of California, as one example, showed serious security vulnerabilities.^[30] Democratic process will require substantive information-accuracy safeguards before a wide move to electronic voting.

PROPERTY

The right to property is largely secured in the legal domain. However, intangibility of information is at the source of dilemmas that take clarity away from the laws, passing many problems into the domain of ethics. At issue are primarily the rights to IP: the intangible property that results from an individual’s or a corporation’s creative activity. The web, which has become a uniquely valuable medium for legitimate distribution of data, information, and knowledge in a digital form, has also become a common means for breaching the rights to this property.

IP, such as software or other digital content, is protected by three legal mechanisms: copyright, patent, and trade secret. These means serve to protect the investment of creators and to ensure public good by encouraging disclosure so that further innovations can be made by others. Indeed, the copyright and patent laws are designed to assist in the public disclosure and thus further technological progress. Copyright registration, which is easy to obtain, protects the form of expression (e.g., a given program) rather than the idea itself (e.g., an algorithm). Because the underlying problem solution is more valuable than its coded expression, this is a limited protection. Patents, which are more difficult to secure, protect novel and nonobvious discoveries that fall in the United States within the subject matter of the U.S. Patent Act. Many patent applications for software failed to prove that they qualify under this “subject-matter” criterion. However, a U.S. Federal Appeals court has affirmed in 1994 the patentability of sufficiently innovative software. Because of the limitations of copyrights and patents with respect to intangible products, software developers most often rely on trade-secret protection. Trade-secret law protects the confidentiality of IP through licenses or nondisclosure agreements.

An elaborate software system is expensive to create. The same software, or another digital product, can be copied at a negligible cost. Such is the nature of IP, which includes software, books, video, and music. Piracy in the form of selling illegally reproduced software has become a serious problem in international trade. In a number of countries, far more than the three quarters of the sales of U.S. software packages are illegal copies. Worldwide software piracy costs the U.S. software industry many billions of dollars annually. Because the legal system trails the pace of technology and because ethical guidance is sought in framing the legal issues, many controversies spill over into the ethical domain.

To “honor property rights” is one of the eight general moral imperatives of the ACM Code of Ethics.

The legal system and ethicists are grappling with many unresolved issues, such as

- To what extent can information and knowledge be considered property?^[31]
- How to reconcile the public’s right to access with the rights to IP and to privacy?
- What makes one digital product distinct from another?
- Would computer-generated works have a human author? If not, how would the property rights be protected?

In the case of property rights to electronic collections of data, such as directories, the U.S. courts have ruled that the copyright law protects only collections that display some creativity in the selection or arrangements of the data and does not protect such labor-intensive but nonoriginal collections as telephone white pages. Yet, the distinctions are often too fine to make a difference.

The industrial ecosystems producing digital goods, such as the music industry, have been transformed by the arrival of the web as a mass medium. Owing to the compression of the content and to the broadband telecommunications technologies, high-quality music and video can be streamed or downloaded. Music and video producers and sellers can be bypassed by consumers communicating in peer-to-peer mode and propagating copies of digital products. The technological domain offers, if only temporarily, a variety of methods of protecting this property, such as digital watermarks, as well as a broad encryption-based technology of digital rights management (DRM). The Digital Millennium Copyright Act, promulgated in 1998 to protect digital property, has made it illegal to circumvent a technological measure that controls access to a protected digital property. Taken together with the DRM technologies, the act goes beyond the preexisting copyright law and is likely to be challenged—justifiably, in much credible opinion.^[32] As we may conclude, many legal issues regarding IP remain unresolved. This is why it is particularly important to approach this property from an ethical standpoint to ensure that our decisions do not violate property rights of others.

ACCESS

It is a hallmark of an information society that access to information and knowledge is mediated by IT, notably the Internet–web, most of the workforce is employed in the processing of information and transformation of knowledge, and most of the goods and services available for consumption are information-related. To gain full access to the benefits of such a society, an individual must possess at least four things: 1) the intellectual skills to deal with information; 2) access to IT, including the Internet–

web; 3) access to information; and 4) access to a free expression over the digital media. If we consider these issues on national and global scales, we see that inequalities persist. Because each of us in a human society draws an economic benefit from the equality of opportunity and because each of us is ethically concerned about fairness, the issue of capable access to information and IT redefines our concern for literacy.

IT does not have to be a barrier to opportunities. Quite the contrary, when deployed purposefully, it can *provide* opportunities not previously accessible. Internet access can bring the contents of the world’s libraries, participation in the world’s markets, and the advice of the world’s experts to a remote location. Intensive work is being done on developing assistive technologies that enhance access of the handicapped to the IT, and, thus, in many cases, to the social and economic mainstream. Assistive technologies for the blind include screen displays that work in an auditory mode through screen-reading software and speech synthesizers, and screens that work in a tactile mode with the use of a Braille display. Access to trustworthy electronic virtual communities, designed with ethical principles in mind, is a great source of support to people bearing afflictions.^[33]

Indeed, with the phenomenal growth of shared computational resources, PCs, smart mobile devices, and of the Internet–web services, the accessibility of IT has grown vastly. But it has not grown equally. Access to the Internet is necessary to participate in the benefits of an information society and economy. Yet, several regions of the world, notably many of the countries of sub-Saharan Africa, remain with limited access. Significant digital divide persists between the developed and poor countries both in the information technologies and complementary assets, such as qualified professionals. Various digital divides also exist in developed countries. Action to eradicate these divides and expand the domain of inclusion in the Internet benefits is an important ethical concern.

Another ethical concern is the expansion of access to the content available online. The claims of IP have to be balanced by the needs of expanding the commonwealth of accessible knowledge and information.^[34] The One Laptop per Child global initiative brings low-cost laptop computers, connected to the web, within the reach of children in poor countries. The Digital Commons initiative provides open access to the knowledge contributed by scholarly journals, as well as to the books not protected by copyright. The movement toward open source and free software makes both the digital products and the tools for their further development accessible to all. A broad understanding of access is gaining worldwide support.

Numerous countries limit their citizens’ access to free expression over the web, erecting digital firewalls to filter and limit the content. Considering the power of the smartphone-armed citizens to organize disrupt dictatorial regimes, this is not surprising. The conscience of the IT professionals—and their ethics codes—will guide them on how to render their service.

MAKING ETHICAL DECISIONS

Let us consider how to make decisions applying ethical principles in the information-related domains—and then apply them to the scenarios presented earlier. The following decision-making sequence can be adopted:

- Examine the issues to see whether they fall in the ethical domain. Seek appropriate professional guidance if the issues seem to be in the legal domain. Apply the “sunshine test” to see whether the issue is ethical or discretionary: Would your decision withstand public disclosure?
- If you believe that ethical issues are involved, would a course of action you are considering violate individual rights? Would the action violate a professional code of ethics?
- Choose the course of action that would not result in an ethical breach.

Let us now view, in this light, our three scenarios presented earlier.

Transactional Information on Smart Cards

The ethical issue of privacy is involved. The legality of the action can be challenged. However, it is obvious that the developers and the users of the system invaded privacy of the debit-card holders with the system that gathered and released data about them without their knowledge. People may consent to their personal data being stored for a specific purpose; however, no such consent was sought. The individuals were also deprived of their right to inspect and, if appropriate, correct their personal data. Furthermore, the financial institution’s prospective plans imply an even broader breach of privacy by indiscriminate, uncontrolled release of transactional information to third parties and should not be pursued. A breach of ethics may have financial consequences to all parties. A possible consumer outcry may render the system useless. Such an argument may indeed carry the day, if you need to defend your recommendation to not go ahead with developing a similar system.

Who Owns E-Mail?

Certainly, the management decision to allow employees the use of the company-owned computers and systems for private purposes violates no ethical principles. We could judge this to be a discretionary action and not an ethics issue. An employee stands in a different relationship to a workplace than a consumer does to a marketplace. But the monitoring action was taken without employees’ knowledge and clearly it is a violation of their right to privacy and, thus, highly unethical if there was a justified

presumption of privacy. However, employers have a right to set policy—and an obligation to make the employees aware of their terms of employment. Should you, as an employer, wish to pursue this course of action, such acceptable use policy has to be drawn up. Perhaps the employees should be able to label certain communications as private, with the employer undertaking an obligation to respect their rights. The least invasive forms of computer-based work monitoring should be adopted. Thus, monitoring of performance, rather than of behaviors or personal characteristics, is preferred.

Let’s Just Release This System

The vice president not only made a poor business decision (that would place the issue in the discretionary domain). By knowingly forcing the development of a defective system, he violated his duty to do what is right. What about the action of the project leader? The ACM Code obligates a professional to “give comprehensive and thorough evaluations of computer systems and their impacts, including analysis of possible risks.”^[2] The project leader failed to do so in this case by agreeing to implement a defective system and by failing to call her superior’s action to the attention of higher authorities.

These three scenarios show that ethical decision-making protects not only professional integrity and upholds the social contract. The expediency of “cutting ethical corners” often produces adverse business results.

CONCLUSION

Information technologies have the power to affect significantly the quality of our personal and working lives. Therefore, all knowledge workers and system users, and particularly computing professionals, face IT-related problems whose solution involves ethical considerations. Purely technological or legal means of protecting individual rights affected by information systems are insufficient in separation from the tenets of infoethics.

The four principal infoethical issues, privacy, accuracy, property, and access, are subjects of professional and organizational codes of ethics, which should be familiar to computer professionals. Our lives have been vastly enriched by the ability to form relationships and express ourselves on social media and social network sites, to form and nurture e-commerce enterprises, and to educate and entertain ourselves online. In the workplace, the use of IT may have positive or negative impacts on the worker, depending on the way the technology is deployed. Potential positive impacts include the increased ability to develop and exercise individual skills, and integration of work into meaningful tasks that can be performed with a large degree of autonomy. Potential negative impacts include reducing skills, routinization of work, and

excessive monitoring of workers. Computer-based performance monitoring should be made the least invasive and should be organized in accordance with ethical principles. Infoethical principles should be inculcated in the workplace as a component of the corporate culture. Ethical practices can and should be incorporated in the software engineering and other computer science curricula.^[35] On the deeper level, our moral lives require reexamination in the face of the new technologies that confront our ethical principles.^[36]

An information society both drives and is driven by incessant innovation. Emerging technologies present threats to the ethical uses of information systems, as well as the means to deal with these threats.^[37] Beyond that, they offer the promise of a better life in an increasingly more inclusive global society. The proper deployment of emerging technologies has to be informed by the decision-making processes keeping in view the ethical issues raised by information systems.

Ethiopia: Libraries, Archives, and Museums

Shiferaw Assefa

University of Kansas, Lawrence, Kansas, U.S.A.

Abstract

This entry explores the historical development of the national, public, academic school and special libraries, museums and galleries in Ethiopia. The country's effort to collect and preserve its documentary heritage started during the Aksumite period (fourth to eighth century A.D) and continued informally until the National Library was established in 1944. Since then, public and other types of libraries have been established and modestly expanded in the country. In addition, the collection and preservation of cultural objects and the development of museums and galleries goes back to the same Aksumite period when churches and monasteries served as custodians and preservers of these objects. The growth of museums and galleries can initially be attributed to the interest demonstrated for Ethiopian cultural and historical objects by foreigners who came to Ethiopia and to the archaeological discoveries carried out by different expeditions during the time of Menelik II (1889–1913) and thereafter. Since then, there has been a fairly slow growth of museums and galleries in the country as a result of an acute shortage of financial resources and trained manpower.

HISTORICAL INTRODUCTION

Ethiopia is located in the horn of East Africa. It lies between latitudes 3°15' and 18° north of the equator and between 33° and 48° to the east of the Meridian. It is bordered by the Sudan on the west, Somalia and Djibouti on the east, Eritrea on the north, and Kenya on the south. The country has been called a cultural mosaic, due to its 80 different languages and dialects and as many, if not more, cultural varieties. The languages found in the country belong to the two major phyla found in Africa: Afro-Asiatic and Nilo-Saharan. The Afro-Asiatic phylum includes the majority of the languages of Ethiopia: the Ethio-Semitic languages of which Amharic and Tigrinya are the best known and the largest members, Cushitic, of which the major languages are Oromo and Somali, and Omotic languages that are entirely spoken in Ethiopia of which Wolaytta is the largest one.^[1] The Nilo-Saharan languages found in the country include Berta, Suri, Me'en, Murle, Kwegu, Majang, and others.

Ethiopia is one of the oldest nations in the world, with great antiquities, cultures, and traditions stretching back 3000 years. It is one of the world's great crossroads, where the peoples and cultures of Africa, the Middle East, and the Mediterranean have interacted for thousands of years. The history of Ethiopia as an organized polity began around 100 B.C. in the northern region of the country. One of the most powerful early kingdoms of Ethiopia was the kingdom of Aksum, which had a complex society. During Aksum's prosperous centuries, it enjoyed contacts with the Mediterranean world, the Nile Valley, and the Indian Ocean as far as China.^[2] Archaeological findings attest to the prosperity of Aksum by the third and fourth century C.E.

The Aksumite kingdom had its own urban centers, coinage in gold, silver, and bronze, buildings, exceptional monuments, and extensive trade contacts within Africa and beyond. Trade most likely was the main source of the kingdom's revenue and wealth. Its exports included ivory, rhinoceros horn, live animals, aromatic spices, and frankincense. Aksum started to decline during the seventh century C.E. as a result of: (1) the rise of Islam in the Arabian Peninsula, which limited its access to the sea; (2) geographical degradations in the capital and surrounding areas; and (3) internal political troubles.^[3] This forced the power and the capital to move to the south and a new dynasty known as the Zagwe Dynasty (Cushitic speaking) came to power around 1137 C.E. It ruled the country until 1270. As devout Christians, the rulers of the Zagwe Dynasty constructed churches and monasteries including the rock-hewn churches of Lalibela. The southward expansion continued for several centuries. In 1270 C.E., power was transferred from the Cushitic speaking people to the Amhara, another Semitic speaking group. The Amhara stayed in power until the Imperial government of Haile Selassie was overthrown by the military in 1974. The current government came to power after it had defeated the military government of Mengistu Hailemariam in 1991. Throughout the history of the country, contacts between the Semitic, Cushitic, and other ethnic groups found in the country continued as the capital moved further south and the kingdom expanded and created a unique cultural diversity. This resulting ethnic and cultural diversity has given rise to many unique and dynamic visual traditions. Ethiopia has also had its own language and its own script for more than 2000 years. Inscriptions on stones that were crafted in the first century C.E. testify to the antiquity of writing.

In addition, for more than 1500 years quite a number of manuscripts (the very earliest ones on vellum) were produced.

Ethiopia accepted Christianity in the fourth century C.E. As a result, many churches were built and a significant number of religious texts were translated into Geez, the liturgical language. Eminent church scholars attracted disciples, and centers of learning developed where calligraphy, manuscript illumination, music, and poetry were taught. Each church and monastery retained a collection of religious literature used for services, teaching, and scholarship.^[4] Hence, the churches, monasteries, and a few respected elderly church dignitaries served as the custodians of the manuscripts and literary works of the country. This trend continued until 1863 when Emperor Thewodros II (1855–1868) put together the largest and the finest collection of Ethiopian manuscripts that well exceeded 981^[4] from the donation of a church at his mountain fortress of Magdalla. The manuscripts were collected from churches, monasteries, and individuals. They were, however, seized by the British when Thewodros was defeated in 1868. The Napier expedition that defeated the king destroyed many manuscripts and looted several others. Some of these manuscripts were returned to Ethiopian Churches while others were kept by the British officers and soldiers. Some 350 came into the possession of the British Museum.

Although the printing of Ethiopic texts in Europe dates back to the late fifteenth century in Mainz, Germany (in the woodcut specimen by Erhard Reuwich),^[5] print technology was not introduced in Ethiopia until the reign of Thewodros. The first printing machine was established at Macaw on the Red Sea coast in 1863.^[4,6,7] When we look closely at the establishment of printing machines in Ethiopia, we find that all of them were primarily introduced to produce religious materials for the consumption of the local people. However, in the beginning of the twentieth century, increased contacts with the outside world made secular education necessary. The country started to build elementary schools. With the increasing number of schools, the need for textbooks also grew. This in turn encouraged the government to establish its own printing press in 1921 in Addis Ababa (the capital city of Ethiopia) which was called Berhanena Selam in 1923.^[7] Although Ethiopia has a long history of language, script, and manuscripts, the history of printing and publishing is very short. The real development of printing started in the twentieth century, and proceeded very slowly. More and more printed materials began to emerge in the early 1930s to serve the erudite Ethiopians and foreigners that resided in the country. This advanced the idea of organizing a central reading room, collecting and making accessible all materials which existed in print.

In 1936, the then emperor Haile Selassie I, commenced a small library with books he collected in different European languages which either he bought or was presented

with.^[8] However, these were only accessible to people in his closest circle.

In another development, Italians who occupied the country during World War II from 1936 to 1941 organized a Central Government Library in Addis Ababa for Italian East Africa, which also included Ethiopia, Eritrea, and Italian Somaliland with a branch in Asmara, the current capital of Eritrea.

LIBRARIES

The National Library and the Development of Public Libraries

The national library

Research shows that efforts to collect and keep in one center the country's documentary heritage dates back to the Aksumite era (the kingdom that flourished between the fourth and eighth centuries A.D.), and churches and monasteries were used to produce manuscripts and to serve as the first "traditional" libraries or storage houses as indicated earlier. However, the intent to organize a National Library commenced only during the time of Emperor Menelik II (1844–1913).^[8] His effort to establish a National Library did not come to fruition for reasons not known. After quite some time had elapsed, "Yehizb Meshaf Bet," and now the National Archives and Library of Ethiopia (NALE) [formerly known as National Library of Ethiopia (NLE)], was established on May 5, 1944. Its foundation signifies the beginning of the modern library in Ethiopia. In his speech to announce the establishment of the National Library, Haile Selassie emphasized that he laid the foundation of the National Library for the liberation of the minds of his people.^[9]

Serke Berhan Gebreegzy was appointed as the first director of the organization. The initial collection of the library came largely from the East African Italian Government Library. At its inception, the National Library was under the auspices of the Antiquities Administration and had two divisions: the public library and the research library. The public library division was the most important resource for the city of Addis Ababa. One of the functions the National Library was to serve as a Central Lending Public Library. It also had a children's collection housed in a separate building. Finally, in the 7 years preceding the revolution (1967), the public library division embarked upon opening one library per year in a provincial town in order to organize a public library system.^[9] The research library division contained materials and books that were transferred from the colonial collection, United Nations documents received on deposit, a number of manuscripts, an Ethiopian Studies collection, and books published in Ethiopia acquired from publishers on the basis of a letter from the Ministry of the Pen requesting the five printing

houses to deposit to the library three copies of every title printed (in 1951). Since this was not promulgated by a separate act of parliament, it could not be enforced. Thus, the lukewarm and spontaneous response from the publishers resulted in the acquisition of few publications.

In the early days of the Ethiopian revolution, the libraries were threatened to be purged in order to get rid of “reactionary” literature. However, to the credit of heads of the different libraries and other intellectuals, books and other materials were not destroyed. More importantly, in 1975 the National Library came under the Department of National Library and Archives of the Ministry of Culture and Sports with four divisions: the public library, the technical services, national library, and archives. The overall objectives of the department were to serve as the center of studies and bibliographic information, to play a central role in leading and coordinating libraries in the country, and to serve the nation as a whole.^[10]

The most important development in the history of libraries in the country was the Legal Deposit Proclamation no. 50 of 1976, which required all printed matter to be deposited in three copies in the National Library.^[10] This has allowed the library to increase the gathering of book and other published material tremendously. The current collection includes 58,854 books, 33,627 periodicals, 859 manuscript, 9239 microfilms, 2650 bound newspapers, and 4408 CDs, audios, and videos.^[10]

Since the establishment of the National Library, three problems have hindered it from achieving its goals: shortage of financial resources, dearth of qualified professional librarians, and space to catalog and store the materials acquired. These problems and others, except the problem of space, still prevail.

The acquisition of library materials for the National Library significantly benefited from the project sponsored by the United States for the microfilming, cataloging, repair, and return of manuscripts in churches and monasteries in Ethiopia. This project was launched in 1971 and steadily continued the filming of manuscripts from church and monastic libraries, private libraries, souvenir shops, and bazaars. For a long time, the copies of the microfilms were housed in the Ministry of Culture which created the Microfilm and Microfiche section of the Department of Libraries and Archives. They were also accessible for viewing for the public.^[11] In 1987, the NALE was newly reorganized to incorporate and assume the responsibilities of the former Ethiopian Microfilm and Microfiche Library in addition to its function as a Department of Library and Archives under the Ministry of Information and Culture.

Since the 1980s, the Legal Deposit and Bibliography section of the Department of Libraries and Archives has published a series of bibliography indexes in Amharic and English entitled “Ethiopian Publications.” The indexes are similar to those that are produced by the university library as mentioned below. They list all materials published in

the country and abroad about Ethiopia, collected annually by the Legal Deposit and Bibliography section.

The National Library has taken on broader duties and responsibilities imposed upon it despite the sector not having been given enough attention to play a proper role in the country’s social and economic activities. Now the organization, by proclamation 191/1999, has been authorized to receive three copies of every item published in the country, including visual and audiovisual materials, as legal deposit. These then form the basis of the bibliographical indexes called “Ethiopian Publications.” NALE also serves as a registry of ISBN and ISSN numbers in order to create a union catalog in the country. In addition to acquiring materials by being the legal depository of the country, NALE gathers documents through purchase and donations. Other numerous duties were also assigned to the organization, such as serving as an information center and being the treasury of Ethiopian literary heritage, which requires the collecting of oral traditions including poems, hymns, and proverbs.

Much has been done to tackle the problems of libraries and archives. Special attention has been given to the development of libraries. NALE was established to serve as an information center and has become accountable to the profession at the national level. Other duties of the NALE staff include the editing, publishing, and distribution of the National Bibliography and periodicals index publications.^[10] NALE is also required to serve as a training center. Moreover, NALE is accorded the responsibility of acquiring and returning to the country the originals or the copies of the priceless literary heritage of the country that have been taken out of the country.

The formation and growth of this information center can play a vital role in the country’s development. NALE, in cooperation with the World Bank, inaugurated its Development Information Service Center in 2004 with duties that include: providing Internet access to the library users; providing information on the activities and mission of the World Bank; and making available up-to-date information on HIV/AIDS prevention programs.

Some of the major problems that continue at the NALE are limited financial resources; shortage of trained professional librarians and archivists; scarcity of modern computers and other types of machinery that could be used by technical services and library patrons; and much needed space for more storage, work space, public use areas, and offices.^[8] The idea to construct a new building and to move the collection into this building came up in the 1950s, but it did not materialize until 2006. With the help of various sponsors and nongovernmental organizations, a corner stone was laid in 2002. The construction work began toward the end of the year and was completed in August 2006.^[13] This temporarily solved the space problem that National Museum had for a long time.

The development of public libraries

The number of public libraries found in Ethiopia has now reached 249 (IFLA 2007).^[8] Interestingly enough, 100 of these libraries are located in Addis Ababa.^[13] Their sizes and collection of items varies greatly. As indicated earlier, the major functions of the National Library are providing service to the public and the development and expansion of public libraries in the country. In this regard, the public library division continued to render service to the public and promoted the expansion of public libraries in the southern part of the country, whereas the new technical services division was assigned to acquire and catalog for the National Library and for the public library in Addis Ababa. The plan was to extend its cataloging expertise to other public library branches located outside the capital city. Currently, there seems to be a concentrated effort to expand public libraries in the regional and rural areas of the country. The users of the majority of the public libraries are high school and college students from the surrounding areas. The major problems that the public libraries face today are limited financial resources, lack of trained librarians, and a shortage of space.

Academic Libraries

The Addis Ababa University (AAU), the oldest institution of higher education in the country, was established in

1950. Its library system is the largest in Ethiopia. It was established in 1961 (Fig. 1). The library system has seven branches, including law, medical, engineering, science, agriculture, and public health. The library has a collection of over half a million items.^[12,13] The main library and some of the branches serve patrons 24 hr a day.

The main library has computers for users to access the library's catalog and also houses about 12 computers usually reserved for graduate students. In addition, the current government has opened a number of public universities in the different regions of the country with various subject specialties.^[14] Moreover, quite a number of private universities have also been created.

As far as the development and growth of academic libraries in Ethiopia are concerned, we need to touch upon the collection of AAU [first known as University College of Addis Ababa (UCAA)], which was then named in the 1960s as Haile Selassie I University and other regional universities found in the country. A unique competitive relationship exists between the University College of Addis Ababa Library and the National Library. The UCAA Library was established in the 1950s and it employed well-qualified librarians. Its collection exceeded that of the National Library in a short period of time as a result of the donations it received. Over time, the UCAA collection became more important for research purposes than that of the National Library. Interestingly, it was the UCAA library that held the first exhibition of books published in Amharic (the national language) and later

Fig. 1 F. Kennedy Memorial Library of Addis Ababa University.

made available its first bibliography in 1964.^[13] The collection of the UCAA library steadily grew whereas that of the National Library grew more slowly.

Other universities outside the capital city that have libraries with significant collections are University of Gondar, Bahir Dar University, Haramaya University, and Jimma University.

The first university library to be discussed is the University of Gondar Library. The University of Gondar is located 738 km from the capital city. The City of Gondar was the capital city of Ethiopia from 1636 to 1868. The University was inaugurated in 2004. It is an expansion of the former Gondar College of Medical Sciences that was established in 1954. The college library was also founded in the same year in order to serve the health professionals trainees, the faculty, and the staff. This is one of the few libraries in the country with “open access” whereby students are allowed to browse the bookshelves by themselves. It also has an online catalog for its users to access the collection. The library houses a good collection of scientific, health, business, and computer science materials. In addition, its collection has strength in information technology, computing, nursing, engineering, and medicine. The total collection of the university exceeds 100,000 items, which includes books, serials, and other materials. The library also offers access to more than 10,000 electronic journals, electronic books, video programs, slide images, and track music.^[15]
